

Test 3 solutions (= version)

1. (15 points) Consider the vector field

$$\begin{aligned} > \mathbf{F} := (\mathbf{x}, \mathbf{y}) \rightarrow [1 + \sin(\mathbf{y})^2, \mathbf{x} \sin(2 \cdot \mathbf{y}) + 1]; \\ & \mathbf{F} := (x, y) \rightarrow [1 + \sin(y)^2, x \sin(2y) + 1] \end{aligned} \quad (1)$$

a) Is there a scalar function $f(x,y)$ for which $F = \text{grad } f$?

This requires that the partials

$$\begin{aligned} > \text{diff}(1 + \sin(\mathbf{y})^2, \mathbf{y}); \text{diff}(\mathbf{x} \sin(2 \cdot \mathbf{y}) + 1, \mathbf{x}); \\ & 2 \sin(y) \cos(y) \\ & \sin(2y) \end{aligned} \quad (2)$$

are equal, which they are, thanks to one of the trig identities you were reminded of.

b) If there is such a function, find it. If there is not, change the coefficient of i so that there is such a function:

There is. To find it we integrate P in x and Q in y . Maple does not add the $+f(y)$ and $+h(x)$ to these:

$$\begin{aligned} > \text{int}(1 + \sin(\mathbf{y})^2, \mathbf{x}); \text{int}(\mathbf{x} \sin(2 \cdot \mathbf{y}) + 1, \mathbf{y}); \\ & (1 + \sin(y)^2) x \\ & -\frac{1}{2} x \cos(2y) + y \end{aligned} \quad (3)$$

Using the identity that $\cos(2y) = 1 - 2 \sin(y)^2$, we need

$$x + x \sin(y)^2 + f(y) = -x/2 + x \sin(y)^2 + y + h(x)$$

By comparing the two sides we see that $f(y) = y + \text{constant}$ and $h = 3x/2 + \text{const}$. A suitable function f is therefore

$$\begin{aligned} > \mathbf{f} := (\mathbf{x}, \mathbf{y}) \rightarrow \mathbf{x} + \mathbf{y} + \mathbf{x} \sin(\mathbf{y})^2; \text{diff}(\mathbf{f}(\mathbf{x}, \mathbf{y}), \mathbf{x}); \text{diff}(\mathbf{f}(\mathbf{x}, \mathbf{y}), \mathbf{y}); \\ & \mathbf{f} := (x, y) \rightarrow x + y + x \sin(y)^2 \\ & 1 + \sin(y)^2 \\ & 1 + 2x \sin(y) \cos(y) \end{aligned} \quad (4)$$

you could add any constant to this f and still be correct.

c) Write a differential equation the solutions of which are $f(x,y) = c$.

In differentials, the answer would be

$$(1 + \sin(y)^2) dx + (x \sin(2y) + 1) dy = 0$$

so in the form asked for we have

$$dy/dx = - (1 + \sin(y)^2) / (x \sin(2y) + 1) .$$

2. (15 points) Find the point on the surface $z = \sqrt{11 + x^2 + y^2}$ which is closest to $(8,6,0)$.
 An equivalent constraint is $g(x,y,z) = 11$,
 where

$$\begin{aligned} > \mathbf{g := (x,y,z) -> z^2 - x^2 - y^2;} \\ & \qquad \qquad \qquad g := (x,y,z) \rightarrow z^2 - x^2 - y^2 \end{aligned} \tag{5}$$

a) A suitable objective function is the distance squared,

$$\begin{aligned} > \mathbf{f := (x,y,z) -> (x-8)^2 + (y-6)^2 + z^2;} \\ & \qquad \qquad \qquad f := (x,y,z) \rightarrow (x-8)^2 + (y-6)^2 + z^2 \end{aligned} \tag{6}$$

b) The system of equations the solution of which answers this question is: $\text{grad } f = \lambda \text{ grad } g$ and also: the constraint equation.

$$\begin{aligned} > \mathbf{with(linalg): grad(f(x,y,z), vector([x,y,z]));} \\ & \qquad \qquad \qquad [2x-16 \quad 2y-12 \quad 2z] \end{aligned} \tag{7}$$

$$\begin{aligned} > \mathbf{grad(g(x,y,z), vector([x,y,z]));} \\ & \qquad \qquad \qquad [-2x \quad -2y \quad 2z] \end{aligned} \tag{8}$$

so:

$$\begin{aligned} > \mathbf{solve(\{2*x-16 = -2*\lambda*x, 2*y-12 = -2*\lambda*y, 2*z = 2*\lambda*z,} \\ & \quad \mathbf{g(x,y,z) = 11\}, \{x,y,z, \lambda\});} \\ & \left. \begin{aligned} z=0, y = \frac{3}{5} \text{RootOf}(11 + _Z^2, \text{label} = _L2), \lambda = -\frac{10}{11} \text{RootOf}(11 \\ + _Z^2, \text{label} = _L2) - 1, x = \frac{4}{5} \text{RootOf}(11 \\ + _Z^2, \text{label} = _L2) \end{aligned} \right\}, \{y=3, \lambda=1, z=6, x=4\}, \{y=3, \lambda=1, z=-6, x=4\} \end{aligned} \tag{9}$$

The unit vector The possibilities with $z=0$ are not real numbers, so

c) The nearest point is $(4,3,6)$.

3. (15 points) Calculate the volume of the solid defined by:

$$0 \leq z \leq 9 - y \exp(2x), \quad 1/2 \leq x \leq 1, \quad -1 \leq y \leq 1$$

This is a double integral,

$$\begin{aligned} > \mathbf{int(9 - y*\exp(2*x), x=1/2..1);} \\ & \qquad \qquad \qquad \frac{9}{2} - \frac{1}{2} y e^2 + \frac{1}{2} y e \end{aligned} \tag{10}$$

$$\begin{aligned} > \mathbf{int(\%, y=-1..1);} \\ & \qquad \qquad \qquad 9 \end{aligned} \tag{11}$$

4. (15 points - aren't you glad you did #16 on p. 980?) Let Ω be the triangle formed by the x-axis and the lines $y = 3 - x$, and $x = 2$.

Calculate one of the following:

> **Int(Int(exp(-x^2), x=y/3..2), y=0..6);**

$$\int_0^6 \int_{\frac{1}{3}y}^2 e^{-x^2} dx dy$$

(12)

or

> **Int(Int(exp(-x^2), y=0..3*x), x=0..2);**

$$\int_0^2 \int_0^{3x} e^{-x^2} dy dx$$

(13)

> **int(int(exp(-x^2), y=0..3*x), x=0..2);**

$$-\frac{3}{2} e^{(-4)} + \frac{3}{2}$$

(14)
