

Test 3 solutions (= version)

1. (15 points) Find the point on the surface $z = \sqrt{3 + x^2 + y^2}$ which is closest to $(6, 4, 0)$.
An equivalent constraint is $g(x, y, z) = 3$,
where

$$\begin{aligned} > \mathbf{g} := (\mathbf{x}, \mathbf{y}, \mathbf{z}) \rightarrow \mathbf{z}^2 - \mathbf{x}^2 - \mathbf{y}^2; \\ & \qquad \qquad \qquad g := (x, y, z) \rightarrow z^2 - x^2 - y^2 \end{aligned} \tag{1}$$

a) A suitable objective function is the distance squared,

$$\begin{aligned} > \mathbf{f} := (\mathbf{x}, \mathbf{y}, \mathbf{z}) \rightarrow (\mathbf{x}-6)^2 + (\mathbf{y}-4)^2 + \mathbf{z}^2; \\ & \qquad \qquad \qquad f := (x, y, z) \rightarrow (x-6)^2 + (y-4)^2 + z^2 \end{aligned} \tag{2}$$

b) The system of equations the solution of which answers this question is: $\text{grad } f = \lambda \text{ grad } g$ and also: the constraint equation.

$$\begin{aligned} > \mathbf{with}(\mathbf{linalg}): \mathbf{grad}(f(\mathbf{x}, \mathbf{y}, \mathbf{z}), \mathbf{vector}([\mathbf{x}, \mathbf{y}, \mathbf{z}])); \\ \text{Warning, the protected names norm and trace have been redefined and unprotected} \end{aligned} \tag{3}$$

$$[2x - 12 \quad 2y - 8 \quad 2z]$$

$$\begin{aligned} > \mathbf{grad}(g(\mathbf{x}, \mathbf{y}, \mathbf{z}), \mathbf{vector}([\mathbf{x}, \mathbf{y}, \mathbf{z}])); \\ & \qquad \qquad \qquad [-2x \quad -2y \quad 2z] \end{aligned} \tag{4}$$

so:

$$\begin{aligned} > \mathbf{solve}(\{2*\mathbf{x}-12 = -2*\mathbf{lambda}*\mathbf{x}, 2*\mathbf{y}-8 = -2*\mathbf{lambda}*\mathbf{y}, 2*\mathbf{z} = 2*\mathbf{lambda}*\mathbf{z}, \\ & \mathbf{g}(\mathbf{x}, \mathbf{y}, \mathbf{z}) = 3\}, \{\mathbf{x}, \mathbf{y}, \mathbf{z}, \mathbf{lambda}\}); \\ & \left. \begin{aligned} & \left. \left. \left. \left. z=0, y=2 \text{RootOf}\left(3 + 13 _Z^2, \text{label}=_L1\right), \lambda = -\frac{26}{3} \text{RootOf}\left(3 \right. \right. \right. \right. \\ & \left. \left. \left. \left. + 13 _Z^2, \text{label}=_L1\right) - 1, x=3 \text{RootOf}\left(3 \right. \right. \right. \right. \\ & \left. \left. \left. \left. + 13 _Z^2, \text{label}=_L1\right) \right\}, \{z=4, \lambda=1, x=3, y=2\}, \{z=-4, \lambda=1, x=3, y=2\} \end{aligned} \right\} \end{aligned} \tag{5}$$

The unit vector The possibilities with $z=0$ are not real numbers, so

c) The nearest point is $(3, 2, 4)$.

2. (15 points) Consider the vector field

$$\begin{aligned} > \mathbf{F} := (\mathbf{x}, \mathbf{y}) \rightarrow [\mathbf{y} * \mathbf{sin}(2*\mathbf{x}) - 1, 1 + \mathbf{sin}(\mathbf{x})^2]; \\ & \qquad \qquad \qquad F := (x, y) \rightarrow [y \sin(2x) - 1, 1 + \sin(x)^2] \end{aligned} \tag{6}$$

a) Is there a scalar function $f(x, y)$ for which $F = \text{grad } f$?

This requires that the partials

$$\begin{aligned} > \mathbf{diff}(\mathbf{y} * \mathbf{sin}(2*\mathbf{x}) - 1, \mathbf{y}); \mathbf{diff}(1 + \mathbf{sin}(\mathbf{x})^2, \mathbf{x}); \\ & \qquad \qquad \qquad \sin(2x) \\ & \qquad \qquad \qquad 2 \sin(x) \cos(x) \end{aligned} \tag{7}$$

are equal, which they are, thanks to one of the trig identities you were reminded of.

b) If there is such a function, find it. If there is not, change the coefficient of i so that there is such a function:

There is. To find it we integrate P in x and Q in y . Maple does not add the $+f(y)$ and $+h(x)$ to these:

```
> int(y* sin(2*x) -1,x); int(1 + sin(x)^2, y);
```

$$-\frac{1}{2}y \cos(2x) - x \left(1 + \sin(x)^2\right)_y \quad (8)$$

Using the identity that $\cos(2y) = 1 - 2 \sin(y)^2$, we need

$$-x -y/2 + y \sin(x)^2 + f(y) = y + y \sin(x)^2 + h(x)$$

By comparing the two sides we see that $f(y) = 3y/2 + \text{constant}$ and $h = -x + \text{const}$. A suitable function f is therefore

```
> f := (x,y) -> -x + y + y*sin(x)^2; diff(f(x,y),x); diff(f(x,y),y);
```

$$f := (x, y) \rightarrow -x + y + y \sin(x)^2 \quad (9)$$

$$-1 + 2y \sin(x) \cos(x)$$

$$1 + \sin(x)^2$$

3. (15 points) Calculate the volume of the solid defined by:

$$0 \leq z \leq 3 + \sin(\pi y), \quad -1 \leq x \leq 2, \quad 1 \leq y \leq 3$$

This is a double integral,

```
> int(3 + sin(Pi*y), x=-1..2);
```

$$9 + 3 \sin(\pi y) \quad (10)$$

```
> int(%, y=1..3);
```

$$18 \quad (11)$$

4. (15 points - aren't you glad you did #16 on p. 980?) Let Ω be the triangle formed by the y -axis and the lines $y = 2x$, and $y = 3$.

Calculate one of the following:

```
> Int(Int(exp(-y^2), x=0..y/2), y=0..3);
```

$$\int_0^3 \int_0^{\frac{1}{2}y} e^{-y^2} dx dy \quad (12)$$

or

> Int(Int(exp(-y^2), y=2*x..3), x=0..3/2);

$$\int_0^{\frac{3}{2}} \int_{2x}^3 e^{-y^2} dy dx$$

(13)

> int(int(exp(-y^2), y=2*x..3), x=0..3/2);

$$\frac{1}{4} - \frac{1}{4} e^{-9}$$

(14)
