1. The Bloch-Floquet Theory
2. Aperiodicity
3. Continuous Fields
4. Dynamical Systems
5. Periodic Approximations for Subshifts
I - The Bloch-Floquet Theory
The Goal

• Compute the spectrum of the *Schrödinger operator* describing the electron motion in a solid

\[ H = -\frac{\hbar^2}{2m}\Delta + \sum_a \sum_{x \in L_a} v_a(\cdot - x) \]  
acting on  
\[ \mathcal{H} = L^2(\mathbb{R}^d) \]

– \( a \) labels the *atomic species*
– \( L_a \) denotes the sets of *positions* of atoms of type \( a \)
– \( v_a \) is the *atomic potential* around an atom of type \( a \)
The Goal

- **Tight-binding representation:** if \( \psi \in \mathcal{H} = \bigoplus_a \ell^2(\mathcal{L}_a) \)

\[
(H\psi)_a(x) = \sum_b \sum_{y \in \mathcal{L}_b} t_{ab}(x, y) \psi_b(y)
\]

The wave function representing the electron is *peaked at each atom* with amplitude \( \psi_a(x) \) if \( x \in \mathcal{L}_a \).
Periodic Materials: Crystals

• There is a co-compact discrete subgroup $G \subset \mathbb{R}^d$ such that translations by elements of $G$ leave the sets $L_a$ invariant for all $a$’s.

• $G$ is unitarily represented in $\mathcal{H}$ and $U(g)H U(g)^{-1} = H$

• Diagonalizing simultaneously $U$ and $H$ leads to

$$\mathcal{H} = \int_{\mathcal{B}} \mathcal{H}_k \, dk \quad H = \int_{\mathcal{B}} H_k \, dk$$

– $\mathcal{B}$ is the Pontryagin dual of $G$, called Brillouin zone,

– $\mathcal{H}_k = L^2(\mathbb{R}^d/G)$ or $\mathcal{H}_k = \bigoplus_a \ell^2(L_a/G)$,

– $H_k$ is the restriction of $H$ to $\mathcal{H}_k$ with $k$-dependent boundary conditions (Bloch boundary conditions).
Periodic Materials: Crystals

- In general, $H_k$ has a *discrete* spectrum depending smoothly on $k$.

- The maps $k \in B \rightarrow E(k) \in \mathbb{R}$ representing the eigenvalues are called *bands*.

- The spectrum of $H$ is the union of the image $E(B)$ over all bands. It is a union of intervals possibly separated by *gaps*.
II - Aperiodicity
Aperiodic Media

- Amorphous materials, silicon, metallic glasses, even liquids.

- Quasicrystal (Shechtman et al., 1984).
The Harper Model

- Perfect *square lattice*, nearest neighbor hoping terms, *uniform magnetic field* $B$ perpendicular to the plane of the lattice
- Translation operators $U_1, U_2$

\[ a = \text{lattice spacing} \]

\[ \phi = \text{flux through unit cell} \]
The Harper Model

- Commutation rules (*Rotation Algebra*)

  \[ U_1 U_2 = e^{2i\pi\alpha} U_2 U_1 \quad \alpha = \frac{\phi}{\phi_0} \quad \phi = B a^2 \quad \phi_0 = \frac{h}{e} \]

- Kinetic Energy (*Hamiltonian*)

  \[ H = t \left( U_1 + U_2 + U_1^{-1} + U_2^{-1} \right) \]

- Landau gauge \( \psi(m, n) = e^{2i\pi m k} \varphi(n) \).

  Hence \( H\psi = E\psi \) means

  \[ \varphi(n + 1) + \varphi(n - 1) + 2 \cos 2\pi(n\alpha - k)\varphi(n) = \frac{E}{t} \varphi(n) \]
Energy levels and wave functions of Bloch electrons in rational and irrational magnetic fields*

Methodologies

• For one dimensional Schrödinger equation of the form

\[ H\psi(x) = -\frac{d^2\psi}{dx^2} + V(x)\psi(x) \]

a transfer matrix approach has been used for a long time to analyze the spectral properties (Bogoliubov ’36).

• A KAM-type perturbation theory has been used successfully (Dinaburg, Sinai ’76, JB ’80’s).
Methodologies

• For discrete one-dimensional models of the form

\[ H\psi(n) = t_{n+1}\psi(n + 1) + t_n\psi(n - 1) + V_n\psi(n) \]

a transfer matrix approach is the most efficient method, both for numerical calculation and for mathematical approach:

– the KAM-type perturbation theory also applies (JB ’80’s).
– models defined by substitutions using the trace map (Khomoto et al., Ostlundt et al. ‘83, JB ‘89, JB, Bovier, Ghez, Damanik... in the nineties)
– theory of cocycle (Avila, Jitomirskaya, Damanik, Krikorian, Gorodesky...).
Methodologies

• In higher dimension almost no rigorous results are available

• Exceptions are for models that are Cartesian products of 1D models (Sire ‘89, Damanik, Gorodestky, Solomyak ‘14)

• Numerical calculations performed on quasi-crystals have shown that
  – Finite cluster calculation lead to a large number of spurious edge states.
  – Periodic approximations are much more efficient
  – Some periodic approximations exhibit defects with contribution to the energy spectrum.
III - Continuous Fields
Warm Up: the Hausdorff Topology

• If \((X, d)\) is a *compact metric* space, the space \(\mathcal{K}(X)\) of compact subsets of \(X\) becomes a compact metric space when endowed with the *Hausdorff metric*

\[
d_H(F, G) = \max\{\delta(F, G), \delta(G, F)\}
\]

\[
\delta(F, G) = \sup_{x \in F} \text{dist}(x, G)
\]

• If \(X\) is only compact and metrizable, a *Haudorff topology* on \(\mathcal{K}(X)\) can similarly be defined, which makes \(\mathcal{K}(X)\) compact and metrizable as well. *(Hausdorff 1914, Vietoris 1922, Fell 1961)*
Warm Up: $C^*$-algebras

A $C^*$-algebra is a complex Banach algebra $\mathcal{A}$ such that

- there is an antilinear involution $a \in \mathcal{A} \mapsto a^* \in \mathcal{A}$ such that,

\[(ab)^* = b^*a^* \quad \|a^*a\| = \|a\|^2\]

for any $a, b \in \mathcal{A}$.

Remark: Such a norm comes only from the algebraic structure

- if $\mathcal{A}, \mathcal{B}$ are two $C^*$-algebras, then any injective $\ast$-homomorphism is isometric

- the norm is the square root of the spectral radius of $a^*a$. 
Continuous Fields of Hamiltonians

\[ A = (A_t)_{t \in T} \text{ is a field of self-adjoint operators whenever} \]

1. \( T \) is a topological space,
2. for each \( t \in T, \mathcal{H}_t \) is a Hilbert space,
3. for each \( t \in T, A_t \) is a self-adjoint operator acting on \( \mathcal{H}_t \).

The field \( A = (A_t)_{t \in T} \) is called \( p2\)-continuous whenever, for every polynomial \( p \in \mathbb{R}(X) \) with degree at most 2, the following norm map is continuous

\[ \Phi_p : t \in T \mapsto ||p(A_t)|| \in [0, +\infty) \]
**Continuous Fields of Hamiltonians**

**Theorem:** (S. Beckus, J. Bellissard ‘16)

1. A field $A = (A_t)_{t \in T}$ of self-adjoint bounded operators is $p_2$-continuous if and only if the spectrum of $A_t$, seen as a compact subset of $\mathbb{R}$, is a continuous function of $t$ with respect to the Hausdorff metric.

2. Equivalently $A = (A_t)_{t \in T}$ is $p_2$-continuous if and only if the spectral gap edges of $A_t$ are continuous functions of $t$. 
The field \( A = (A_t)_{t \in T} \) is called \( p2-\alpha\)-Hölder continuous whenever, for every polynomial \( p \in \mathbb{R}(X) \) with degree at most 2, the following norm map is \( \alpha \)-Hölder continuous

\[
\Phi_p : t \in T \mapsto \|p(A_t)\| \in [0, +\infty)
\]

uniformly w.r.t. \( p(X) = p_0 + p_1 X + p_2 X^2 \in \mathbb{R}(X) \) such that \( |p_0| + |p_1| + |p_2| \leq M \), for some \( M > 0 \).
Continuous Fields of Hamiltonians

Theorem: (S. Beckus, J. Bellissard ‘16)

1. A field $A = (A_t)_{t \in \mathbb{T}}$ of self-adjoint bounded operators is $p2\cdot \alpha$-Hölder continuous then the spectrum of $A_t$, seen as a compact subset of $\mathbb{R}$, is an $\alpha/2$-Hölder continuous function of $t$ with respect to the Hausdorff metric.

2. In such a case, the edges of a spectral gap of $A_t$ are $\alpha$-Hölder continuous functions of $t$ at each point $t$ where the gap is open.

3. At any point $t_0$ for which a spectral gap of $A_t$ is closing, if the tip of the gap is isolated from other gaps, then its edges are $\alpha/2$-Hölder continuous functions of $t$ at $t_0$.

4. Conversely if the gap edges are $\alpha$-Hölder continuous, then the field $A$ is $p2\cdot \alpha$-Hölder continuous.
Continuous Fields of Hamiltonians

The spectrum of the Harper model
the Hamiltonina is $p^2$-Lipschitz continuous

(JB, ’94)
Continuous Fields on C*-algebras

(Tomyama 1958, Dixmier-Douady 1962)

Given a topological space $T$, let $\mathcal{A} = (\mathcal{A}_t)_{t \in T}$ be a family of $C^*$-algebras. A vector field is a family $a = (a_t)_{t \in T}$ with $a_t \in \mathcal{A}_t$ for all $t \in T$. $\mathcal{A}$ is called continuous whenever there is a family $\Upsilon$ of vector fields such that,

- for all $t \in T$, the set $\Upsilon_t$ of elements $a_t$ with $a \in \Upsilon$ is a dense $\ast$-subalgebra of $\mathcal{A}_t$
- for all $a \in \Upsilon$ the map $t \in T \mapsto \|a_t\| \in [0, +\infty)$ is continuous
- a vector field $b = (b_t)_{t \in T}$ belongs to $\Upsilon$ if and only if, for any $t_0 \in T$ and any $\epsilon > 0$, there is $U$ an open neighborhood of $t_0$ and $a \in \Upsilon$, with $\|a_t - b_t\| < \epsilon$ whenever $t \in U.$
Continuous Fields on $C^*$-algebras

**Theorem** If $\mathcal{A}$ is a continuous field of $C^*$-algebras and if $a \in \Upsilon$ is a continuous self-adjoint vector field, then, for any continuous function $f \in C_0(\mathbb{R})$, the maps $t \in T \mapsto \|f(a_t)\| \in [0, +\infty)$ are continuous.

In particular, such a vector field is $p2$-continuous.
Continuous Fields on $\mathbb{C}^*$-algebras

How does one construct a continuous field of $\mathbb{C}^*$-algebras?
IV - Dynamical Systems
Hull

- The set $\mathcal{L}$ of atomic position is Delone:
  - There is a minimum distance $2a$ between two distinct atoms
  - The diameter $2b$ of the largest hole is finite.

- There is a topology on the set $\mathcal{D}_{a,b}$ of Delone sets with given $a, b$ making it a compact second countable space.

- The Hull $\Omega$ of $\mathcal{L}$ is the closure of its orbit under $\mathbb{R}^d$ inside the space of Delone sets. Hence $\Omega$ is a compact second countable space.

- The translation group $\mathbb{R}^d$ acts on $\mathcal{D}_{a,b}$ and on $\Omega$ by homeomorphisms.

- Hence $(\mathcal{D}_{a,b}, \mathbb{R}^d)$ and $(\Omega, \mathbb{R}^d)$ are topological dynamical systems.
Transversal

- The set $\mathcal{D}^0_{a,b} \subset \mathcal{D}_{a,b}$ is defined as the set of Delone sets containing the origin of $\mathbb{R}^d$.

- Given $\mathcal{L} \in \mathcal{D}_{a,b}$ its transversal is defined as $\mathcal{E} = \Omega \cap \mathcal{D}^0_{a,b}$.

- **Assumption:** to avoid technicalities, it will be assumed that there is a co-compact discrete subgroup $G \subset \mathbb{R}^d$, acting on $\mathcal{E}$, with at least one dense orbit.
\textbf{C*-algebras}

Given a topological dynamical system \((X, G)\), where \(X\) is a compact space and \(G\) a unimodular locally compact group, the \textit{reduced crossed product} C*-algebra \(C(X) \rtimes_{\text{red}} G\) is built as follows:

- if \(A, B \in C_c(X \times G)\) of continuous functions with compact support, the \textit{product} is defined by

\[ AB(x, g) = \int_G A(x, h)B(h^{-1}x, h^{-1}g) \, dg \]

- The \textit{adjoint} is defined by

\[ A^*(x, g) = A(g^{-1}x, g^{-1}) \]
**C*-algebras**

- Given \( x \in X \) let \( \pi_x \) be the *representation* of \( C_c(X \times G) \) on \( L^2(G) \) defined by

\[
\pi_x(A)\psi(g) = \int_G A(g^{-1}x, g^{-1}h)\psi(h) \, dh
\]

- Then a *C*-norm is defined by

\[
\|A\| = \sup_{x \in X} \|\pi_x(A)\|
\]

- By completing the space \( C_c(X \times G) \) w.r.t. this norm leads to the \( * \)-algebra \( C(X) \rtimes_{red} G \).
Invariant Subsets

- A subset $F \subseteq X$ is \textit{G-invariant} whenever $x \in F$, $g \in G$ implies $gx \in F$.

- Let $\mathcal{I}_G(X)$ be the set of \textit{closed G-invariant subsets} of $X$.

- Endowed with the \textit{Hausdorff topology}, it is a \textit{compact Hausdorff} space.

- For $F \in \mathcal{I}_G(X)$ let $\mathcal{A}_F = C(F) \rtimes_{\text{red}} G$. This gives a \textit{field} $\mathcal{A} = \{(\mathcal{A}_F)_{F \in \mathcal{I}_G(X)} \}$ of $\mathcal{C}^*$-algebras.
Invariant Subsets

**Theorem:** If $G$ is discrete and amenable, and if $X$ is second countable, then the field \( \mathcal{A} = (\mathcal{A}_F)_{F \in \mathcal{I}_G(X)} \) is continuous.

- If $G = \mathbb{Z}^d$ a point $x \in X$ is **periodic** whenever there is a subgroup $H \subset G$ of **finite index**, such that $hx = x$ for $h \in H$.
- $x$ is periodic if and only if its orbit $O_x = Gx$ is finite and minimal.
- If $F \in \mathcal{I}_G(X)$ is the limit (in the Hausdorff topology) of a sequence $(F_n)_{n \in \mathbb{N}}$ of minimal finite invariant sets, then $\mathcal{A}_F$ is the limit of $\mathcal{A}_{F_n}$ in the sense of continuous fields of $C^*$-algebras.
V - Periodic Approximations for Subshifts
Subshifts: de Bruijn Graphs

Let \( \mathcal{A} \) be a finite alphabet, let \( \Xi = \mathcal{A}^\mathbb{Z} \) be equipped with the shift \( S \). Let \( \Sigma \in J(\Xi) \) be a subshift. Then

- given \( l, r \in \mathbb{N} \) an \( (l, r) \)-collared dot is a dotted word of the form \( u \cdot v \) with \( u, v \) being words of length \(|u| = l, |v| = r\) such that \( uv \) is a sub-word of at least one element of \( \Sigma \)
• an \((l, r)\)-collared letter is a dotted word of the form \(u \cdot a \cdot v\) with \(a \in A\), \(u, v\) being words of length \(|u| = l, |v| = r\) such that \(uav\) is a sub-word of at least one element of \(\Sigma\): a collared letter links two collared dots.
Subshifts: de Bruijn Graphs

- Let $\mathcal{V}_{l,r}$ be the set of $(l, r)$-collared dots, let $\mathcal{E}_{l,r}$ be the set of $(l, r)$-collared letters: then the pair $G_{l,r} = (\mathcal{V}_{l,r}, \mathcal{E}_{l,r})$ gives a finite directed graph. (de Bruijn, '46, Anderson-Putnam '98, Gähler, '01)

- The origin $\partial_0 e$ and the end $\partial_1 e$ are the collared dots to the left and the right of the collared letter $e$

\[ \partial_0 e = u_1 \ldots u_2 u_1 \cdot a v_1 v_2 \ldots v_{r-1} \]
\[ \partial_1 e = u_{l-1} \ldots u_2 u_1 a \cdot v_1 v_2 \ldots v_r \]
The Fibonacci Tiling

- **Alphabet:** \( \mathcal{A} = \{a, b\} \)
- **Fibonacci sequence:** generated by the substitution \( a \rightarrow ab \), \( b \rightarrow a \) starting from either \( a \cdot a \) or \( b \cdot a \)

**Left:** \( G_{1,1} \)

**Right:** \( G_{8,8} \)
The Thue-Morse Tiling

- **Alphabet:** \( A = \{a, b\} \)

- **Thue-Morse sequences:** generated by the substitution \( a \rightarrow ab, b \rightarrow ba \) starting from either \( a \cdot a \) or \( b \cdot a \)
The Rudin-Shapiro Tiling

- **Alphabet:** \( A = \{a, b, c, d\} \)
- **Rudin-Shapiro sequences:** generated by the substitution \( a \rightarrow ab, b \rightarrow ac, c \rightarrow db, d \rightarrow dc \) starting from either \( b \cdot a, c \cdot a \) or \( b \cdot d, c \cdot d \)
The Full Shift on Two Letters

- **Alphabet:** $\mathcal{A} = \{a, b\}$ all possible word allowed.
Strongly Connected Graphs

The de Bruijn graphs are

- **simple**: between two vertices there is at most one edge,
- **connected**: if the sub-shift is *topologically transitive*, (i.e. one orbit is dense), then between any two vertices, there is at least one path connected them,
- has **no dangling vertex**: each vertex admits at least one ingoing and one outgoing vertex,
- if \( n = l + r = l' + r' \) then the graphs \( G_{l,r} \) and \( G_{l',r'} \) are *isomorphic* and denoted by \( G_n \).
A directed graph is called *strongly connected* if any pair $x, y$ of vertices there is an *oriented path* from $x$ to $y$ and another one from $y$ to $x$.

**Proposition:** If the sub-shift $\Sigma$ is minimal (i.e. every orbit is dense), then each of the de Bruijn graph is stongly connected.
Main result:

**Theorem:** A subshift $\Sigma \subset A^\mathbb{Z}$ can be Hausdorff approximated by a sequence of periodic orbits if and only if it admits a sequence of strongly connected de Bruijn graphs.

**Construction:** Periodic approximations can be obtained from *simple closed paths* in the sequence of strongly connected de Bruijn graphs.
Open Problem

Question:

Is there a similar criterion for the space of Delone sets in $\mathbb{R}^d$ or for some remarkable subclasses of it?

Some sufficient conditions have been found for $\Omega = A^G$, where $G$ is a discrete, countable and amenable group, in particular when $G = \mathbb{Z}^d$.

(S. Beckus, PhD Thesis, 2016)
Thanks for listening!
