# ON UNIFORM CONVERGENCE OF DIAGONAL MULTIPOINT PADÉ APPROXIMANTS FOR ENTIRE FUNCTIONS 

D. S. LUBINSKY

#### Abstract

We prove that for most entire functions $f$ in the sense of category, a strong form of the Baker-Gammel-Wills Conjecture holds. More precisely, there is an infinite sequence $\mathcal{S}$ of positive integers $n$, such that given any $r>0$, and multipoint Padé approximants $R_{n}$ to $f$ with interpolation points in $\{z:|z| \leq r\},\left\{R_{n}\right\}_{n \in S}$ converges locally uniformly to $f$ in the plane. The sequence $\mathcal{S}$ does not depend on $r$, nor on the interpolation points. For entire functions with smooth rapidly decreasing coefficients, full diagonal sequences of multipoint Padé approximants converge.

Padé approximation, Multipoint Padé approximants, spurious poles. 41A21, 41A20, 30E10.

## 1. Introduction ${ }^{1}$

Let $D$ be an open connected subset of $\mathbb{C}$, and $f: D \rightarrow \mathbb{C}$ be analytic. Given $n \geq 0$ and $2 n+1$ not necessarily distinct points $\Lambda_{n}=\left\{z_{j}\right\}_{j=1}^{2 n+1}$ in $D$, and

$$
\omega_{n}(z)=\omega_{n}\left(\Lambda_{n}, z\right)=\prod_{j=1}^{2 n+1}\left(z-z_{j}\right)
$$

the $(n, n)$ multipoint Padé approximant to $f$ with interpolation set $\Lambda_{n}$ is a rational function

$$
R_{n}\left(\Lambda_{n}, z\right)=\frac{p_{n}\left(\Lambda_{n}, z\right)}{q_{n}\left(\Lambda_{n}, z\right)}
$$

or more simply,

$$
R_{n}(z)=\frac{p_{n}(z)}{q_{n}(z)}
$$

[^0]where $p_{n}$ and $q_{n}$ are polynomials of degree $\leq n$, with $q_{n}$ not identically zero, such that
$$
\frac{f(z) q_{n}(z)-p_{n}(z)}{\omega_{n}(z)}
$$
is analytic in $D$. The special case where all $z_{j}=0$, gives the Padé approximant $[n / n](z)$. It is easily seen that $R_{n}$ exists and is unique, though $p_{n}$ and $q_{n}$ are not separately unique.

The convergence of Padé and multipoint Padé approximants is a much studied subject, with uniform convergence established for large classes of special functions. One of the pitfalls of the method is the appearance of spurious poles, namely poles that do not reflect the analytic properties of the interpolated function $f$ [1], [2], [5], [8], [12], [14], [22], [23], [24], [27], [29], [30], [31], [33]. For this reason, the most general results, such as the Nuttall-Pommerenke theorem, often involve convergence in capacity, rather than uniform convergence. In 1961, Baker, Gammel, and Wills nevertheless conjectured that at least a subsequence of the diagonal Padé sequence converges locally uniformly. Throughout this paper,

$$
B_{r}=\{z:|z|<r\}, r>0 .
$$

## Baker-Gammel-Wills Conjecture

Let $f$ be meromorphic in $B_{1}$ and analytic at 0 . Then there is a subsequence $\{[n / n]\}_{n \in \mathcal{S}}$ of $\{[n / n]\}_{n \geq 1}$ that converges uniformly to $f$ in compact subsets of $B_{1}$ omitting poles of $f$.

The author showed in 2001 [24] that the conjecture is false, by considering the Rogers-Ramanujan function with a non-standard value of $q$ on the unit circle. While this provided a meromorphic counterexample, A.P. Buslaev quickly followed [6] with an analytic counterexample, formed from an algebraic function, and then showed that even the Rogers-Ramanujan function provides an analytic counterexample [7]. George Baker [3] subsequently noted that for these counterexamples, just two subsequences together provide locally uniform convergence in the unit ball. He went on to conjecture that a patchwork of finitely many subsequences can provide locally uniform convergence for functions meromorphic in the ball [4].

One of the unsolved issues is whether the Baker-Gammel-Wills conjecture is valid for entire functions, or perhaps even functions meromorphic in the plane. To date, there is still no counterexample. The author proved [19] that the Baker-Gammel-Wills conjecture is true for most entire functions in the sense of category.

In this paper, we shall show that a stronger form of the conjecture, allowing interpolation points in any compact set, with the same subsequence, is true for most entire functions in the sense of category. Accordingly, let $\mathcal{A}$ denote the space of entire functions, with metric defined in terms of power series coefficients: if

$$
f(z)=\sum_{j=0}^{\infty} a_{j} z^{j} \text { and } g(z)=\sum_{j=0}^{\infty} b_{j} z^{j},
$$

then define

$$
\begin{equation*}
d^{*}(f, g)=\sup _{j \geq 0}\left|a_{j}-b_{j}\right|^{1 / \max \{j, 1\}} \tag{1.1}
\end{equation*}
$$

Convergence in this space is equivalent to uniform convergence in compact sets. Recall that a subset of $\mathcal{A}$ is of the first category, if it is a countable union of nowhere dense sets. As such, it is small in the sense of category. Recall too that an $F_{\sigma}$ set is a countable union of closed sets.

## Theorem 1.1

There is an $F_{\sigma}$ subset $\mathcal{E}$ of $\mathcal{A}$ of the first category, such that for $f \in \mathcal{A} \backslash \mathcal{E}$, there is an infinite subsequence $\mathcal{S}$ of positive integers with the following property: given any $r>0$ and for $n \in \mathcal{S}$, multipoint Padé approximants $R_{n}$ to $f$ of type $(n, n)$ formed from interpolation points $\Lambda_{n} \subset B_{r}$, we have

$$
\begin{equation*}
\lim _{n \rightarrow \infty, n \in \mathcal{S}} R_{n}(z)=f(z) \tag{1.2}
\end{equation*}
$$

uniformly in compact subsets of the plane.
Observe that while $\mathcal{S}$ depends on $f$, it does not depend on the ball $B_{r}$ in which the interpolation points lie. As far as the author is aware, $e^{z}$ is the only function for which diagonal rational interpolants with interpolation points in any compact set (and that are not restricted to include complex conjugate interpolation points) had been proven to converge locally uniformly [10], [32]. For Markov-Stieltjes functions, convergence of diagonal multipoint Padé approximants, with interpolation points symmetric about the real axis, has been investigated in [9], [13].

We also prove some more explicit results when the Maclaurin series coefficients decay rapidly and/or smoothly:

## Theorem 1.2

Assume that

$$
\begin{equation*}
f(z)=\sum_{j=0}^{\infty} a_{j} z^{j} \tag{1.3}
\end{equation*}
$$

where $a_{j} \neq 0$ for $j \geq 0$ and for some fixed $J$, and for $j \geq J$,

$$
\begin{equation*}
\left|\frac{a_{j-1} a_{j+1}}{a_{j}^{2}}\right| \leq \chi^{2} \tag{1.4}
\end{equation*}
$$

where $\chi<\rho_{0}$ and $\rho_{0}=0.4559 \ldots$ is the positive root of the equation

$$
\begin{equation*}
\sum_{j=1}^{\infty} \rho^{j^{2}}=\frac{1}{2} \tag{1.5}
\end{equation*}
$$

Let $r>0$. For $n \geq 1$, let $R_{n}$ denote a multipoint Padé approximant to $f$ formed with interpolation points in $B_{r}$. Then uniformly in compact subsets of the plane,

$$
\lim _{n \rightarrow \infty} R_{n}(z)=f(z) .
$$

## Theorem 1.3

Assume that $f$ is given by (1.3), where $a_{j} \neq 0$ for $j \geq 0$ and for some $|q|<1$,

$$
\begin{equation*}
\lim _{j \rightarrow \infty} \frac{a_{j-1} a_{j+1}}{a_{j^{2}}}=q \tag{1.6}
\end{equation*}
$$

Then the conclusion of Theorem 1.2 remains valid.
We note that Theorems 1.2 and 1.3 were proved for the special case of Padé approximants in [20], [21]. In [20], the slightly more general condition $\chi \leq \rho_{0}$ was allowed. We note also that Theorems 1.2 and 1.3 and the results of [25] show that given $s>r>0$, then for large enough $n, f-R_{n}$ formed from interpolation points in $B_{r}$, has exactly $2 n+1$ zeros, counting multiplicity, in $B_{s}$. Related results dealing with smooth Maclaurin series coefficients appear in [11], [15], [16], [28]. Without smoothness but with more rapid decay, we prove convergence of a subsequence:

## Theorem 1.4

Assume that for $f$ given by (1.3),

$$
\begin{equation*}
\limsup _{j \rightarrow \infty}\left|a_{j}\right|^{1 / j^{2}}<\frac{1}{3} . \tag{1.7}
\end{equation*}
$$

Then there is a subsequence $\mathcal{S}$ of integers with the property (1.2) as described in Theorem 1.1.

Theorem 1.1 suggests a stronger form of the Baker-Gammel-Wills Conjecture for entire functions:

## Conjecture 1.5

Let $f$ be entire. Then there is an infinite subsequence $\mathcal{S}$ of positive integers with the following property: given any $r>0$ and for $n \in \mathcal{S}$, multipoint Padé approximants $R_{n}$ to $f$ of type $(n, n)$ formed from interpolation points $\Lambda_{n} \subset B_{r}$, we have (1.2).

We close this section with more notation, firstly, finite differences: given distinct $z_{1}, z_{2}, z_{3}, \ldots$, define $f\left[z_{1}\right]=f\left(z_{1}\right)$,

$$
f\left[z_{1}, z_{2}\right]=\frac{f\left(z_{2}\right)-f\left(z_{1}\right)}{z_{2}-z_{1}}
$$

and recursively, for $r \geq 2$,

$$
f\left[z_{1}, \ldots, z_{r+1}\right]=\frac{f\left[z_{1}, \ldots, z_{r-1}, z_{r+1}\right]-f\left[z_{1}, \ldots, z_{r-1}, z_{r}\right]}{z_{r+1}-z_{r}}
$$

When points coalesce, that is not all $\left\{z_{j}\right\}$ are distinct, the finite difference is defined as the appropriate derivative. We also set

$$
\begin{equation*}
f_{i, j}=f\left[z_{i+1}, z_{i+2}, \ldots, z_{j+1}\right] . \tag{1.8}
\end{equation*}
$$

We shall make extensive use of the following formula for the denominator in $R_{n}\left(\Lambda_{n}, z\right)$ when $\Lambda_{n}=\left\{z_{j}\right\}_{j=1}^{2 n+1}[2$, p. 339]:

$$
\operatorname{det}\left[\begin{array}{ccccc}
f_{n, n+1} & f_{n, n+2} & \cdots & f_{n, 2 n} & \prod_{k=1}^{n}\left(z-z_{k}\right) \\
f_{n-1, n+1} & f_{n-1, n+2} & \cdots & f_{n-1,2 n} & \prod_{k=1}^{n-1}\left(z-z_{k}\right) \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
f_{0, n+1} & f_{0, n+2} & \cdots & f_{0,2 n} & 1
\end{array}\right] .
$$

It is valid as long as this last determinant is not identically 0 . By row and column swaps, we can recast it (absorbing a sign change into the
numerator polynomial) as

$$
q_{n}\left(\Lambda_{n}, z\right)=\operatorname{det}\left[\begin{array}{ccccc}
1 & f_{0, n+1} & f_{0, n+2} & \cdots & f_{0,2 n}  \tag{1.9}\\
z-z_{1} & f_{1, n+1} & f_{1, n+2} & \cdots & f_{1,2 n} \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
\prod_{k=1}^{n-1}\left(z-z_{k}\right) & f_{n-1, n+1} & f_{n-1, n+2} & \cdots & f_{n-1,2 n} \\
\prod_{k=1}^{n}\left(z-z_{k}\right) & f_{n, n+1} & f_{n, n+2} & \cdots & f_{n, 2 n}
\end{array}\right]
$$

Throughout this paper, we assume that $f$ is entire, not a polynomial, and has Maclaurin series given by (1.3). The paper is organized as follows: we prove Theorems 1.1 and 1.4 in Section 2, Theorem 1.2 in Section 3, and Theorem 1.3 in Section 4.

## 2. Proof of Theorems 1.1 and 1.4

We begin by bounding coefficients of non-polynomial entire functions, much as in [19]. Let

$$
K=\max \left\{1,\left|a_{0}\right|\right\}
$$

Define an increasing sequence of integers

$$
0=j_{0}<j_{1}<j_{2}<\ldots
$$

and positive numbers $\left\{\rho_{j}\right\}$ as follows: first, choose $j_{1} \geq 1$ such that

$$
\rho_{j_{1}}^{-1}=\left(\frac{\left|a_{j_{1}}\right|}{K}\right)^{1 / j_{1}}=\max \left\{\left(\frac{\left|a_{j}\right|}{K}\right)^{1 / j}: j \geq 1\right\}
$$

Having defined $\rho_{j_{1}}, \ldots, \rho_{j_{k}}$, define $\rho_{j_{k+1}}$ by

$$
\rho_{j_{k+1}}^{-1}=\left|\frac{a_{j_{k+1}}}{a_{j_{k}}}\right|^{\frac{1}{j_{k+1}-j_{k}}}=\max \left\{\left|\frac{a_{j}}{a_{j_{k}}}\right|^{\frac{1}{j-j_{k}}}: j>j_{k}\right\} .
$$

If there is more than one choice of $j_{k}$, choose the largest one. Define

$$
\rho_{n}=\rho_{j_{k+1}} \text { for } j_{k}+1 \leq n \leq j_{k+1} \text { and } k \geq 0
$$

## Lemma 2.1

(a)

$$
\begin{equation*}
\left|a_{n}\right| \leq K / \prod_{\ell=1}^{n} \rho_{\ell}, \text { for } n \geq 0 \tag{2.1}
\end{equation*}
$$

with equality when

$$
n=j_{k} \text { for some } k \geq 1
$$

(b) $\left\{\rho_{k}\right\}$ is an increasing sequence with limit $\infty$.
(c) If $n=j_{k}$ for some $k \geq 1$, then for $r \geq-n$,

$$
\left|\frac{a_{n+r}}{a_{n}}\right| \leq\left\{\begin{array}{cc}
\rho_{n+1}^{-r}, & r \geq 0  \tag{2.2}\\
\rho_{n}^{-r}, & r<0
\end{array} .\right.
$$

## Proof

(a) Suppose that $k$ is given, and $j_{k}+1 \leq n \leq j_{k+1}$. Then by definition of $j_{k+1}$,

$$
\begin{gathered}
\left|\frac{a_{n}}{a_{j_{k}}}\right|^{\frac{1}{n-j_{k}}} \leq \rho_{j_{k+1}}^{-1} \\
\Rightarrow\left|a_{n}\right| \leq\left|a_{j_{k}}\right| \rho_{j_{k+1}}^{-\left(n-j_{k}\right)}=\left|a_{j_{k}}\right| / \prod_{\ell=j_{k}+1}^{n} \rho_{\ell} .
\end{gathered}
$$

We have equality if $n=j_{k+1}$. Applying this inequality recursively to $a_{j_{k}}, a_{j_{k-1}}, \ldots$, we obtain (2.1), with equality if $n$ equals some $j_{k}$, some $k \geq 1$.
(b) Now as $j_{k+2}>j_{k+1}$,

$$
\begin{aligned}
& \rho_{j_{k+1}}^{-1}=\left|\frac{a_{j_{k+1}}}{a_{j_{k}}}\right|^{\frac{1}{j_{k+1}-j_{k}}}>\left|\frac{a_{j_{k+2}}}{a_{j_{k}}}\right|^{\frac{1}{j_{k+2}-j_{k}}} \\
& \left.\quad=\left|\frac{a_{j_{k+2}}}{a_{j_{k+1}}}\right|^{\frac{1}{j_{k+2}-j_{k}}} \right\rvert\, \frac{a_{j_{k+1}}^{a_{j_{k}}}}{a^{\frac{1}{j_{k+2}-j_{k}}}} \\
& \Rightarrow\left|\frac{a_{j_{k+1}}}{a_{j_{k}}}\right|^{\frac{1}{j_{k+1}-j_{k}}-\frac{1}{j_{k+2}-j_{k}}}>\left|\frac{a_{j_{k+2}}}{a_{j_{k+1}}}\right|^{\frac{1}{j_{k+2}-j_{k}}} \\
& \Rightarrow\left|\frac{a_{j_{k+1}}}{a_{j_{k}}}\right|^{\frac{j_{k+2}-j_{k+1}}{j_{k+1}-j_{k}}}>\left|\frac{a_{j_{k+2}}}{a_{j_{k+1}}}\right|^{\frac{1}{j_{k}}} \\
& \Rightarrow\left|\frac{a_{j_{k+1}}}{a_{j_{k}}}\right|^{\frac{1}{j_{k+1}-j_{k}}}>\left|\frac{a_{j_{k+2}}}{a_{j_{k+1}}}\right|^{\frac{1}{j_{k+2}-j_{k+1}}} \\
& \Rightarrow \rho_{j_{k+1}}^{-1}>\rho_{j_{k+2}}^{-1} .
\end{aligned}
$$

The monotonicity of $\left\{\rho_{n}\right\}$ follows, and the fact that $f$ is entire, forces them to have limit $\infty$.
(c) If $r \geq 0$, we have (using that there is equality in (2.1) for $n=j_{k}$ ),

$$
\left|\frac{a_{n+r}}{a_{n}}\right| \leq \prod_{\ell=n+1}^{n+r} \rho_{\ell}^{-1} \leq \rho_{n+1}^{-r} .
$$

If $r<0$, we instead have

$$
\left|\frac{a_{n+r}}{a_{n}}\right| \leq \prod_{\ell=n+r}^{n-1} \rho_{\ell} \leq \rho_{n}^{-r}
$$

We shall frequently use a series expansion for finite differences. Assume $R>0, \ell \geq 1$, and $z_{1}, z_{2}, \ldots, z_{\ell} \in \overline{B_{R}}$. Then by the contour integral representation for finite differences [26, p. 11], if $\Gamma=\{t:|t|=S\}$, where $S>R$, then

$$
\begin{aligned}
f\left[z_{1}, z_{2}, \ldots, z_{\ell}\right] & =\frac{1}{2 \pi i} \int_{\Gamma} \frac{f(t)}{\prod_{k=1}^{\ell}\left(t-z_{k}\right)} d t \\
& =\frac{1}{2 \pi i} \int_{\Gamma} \frac{f(t)}{t^{\ell}} \sum_{i_{1} \ldots i_{\ell} \geq 0} \frac{z_{1}^{i_{1}} z_{2}^{i_{2}} \ldots z_{\ell}^{i_{\ell}}}{t^{i_{1}+i_{2}+. .+i_{\ell}}} d t \\
& =\sum_{i_{1} \ldots i_{\ell} \geq 0} z_{1}^{i_{1}} z_{2}^{i_{2} \ldots z_{\ell}^{i_{\ell}} a_{\ell-1+i_{1}+i_{2}+. .+i_{\ell}}}
\end{aligned}
$$

## Lemma 2.2

Assume that $n=j_{i}$ for some $i \geq 1$, where the $\left\{j_{i}\right\}$ are as above. Assume that all $\left|z_{j}\right| \leq R$ and $\rho_{n}>R$.
(a) Then for $0 \leq j, k \leq n$, with the notation (1.8),

$$
\begin{equation*}
\left(\rho_{n} \rho_{n+1}\right)^{\frac{k-j}{2}}\left|\frac{f_{j, n+k}}{a_{n}}\right| \leq\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{\frac{|k-j|}{2}}\left(1-R / \rho_{n}\right)^{-(n+1+k-j)} \tag{2.4}
\end{equation*}
$$

(b) For $0 \leq j \leq n$,

$$
\begin{equation*}
\left|\frac{f_{j, n+j}}{a_{n}}-1\right| \leq\left(1-R / \rho_{n+1}\right)^{-(n+1)}-1 \tag{2.5}
\end{equation*}
$$

## Proof

(a) Let $\ell=n+1+k-j$. From the series (2.3) above

$$
\begin{align*}
\left|\frac{f_{j, n+k}}{a_{n}}\right| & =\left|\sum_{i_{1} \ldots i_{\ell} \geq 0} z_{j+1}^{i_{1}} z_{j+2}^{i_{2}} \ldots z_{j+\ell+1}^{i_{\ell}} \frac{a_{\ell-1+i_{1}+i_{2}+\ldots+i_{\ell}}}{a_{n}}\right| \\
& \leq \sum_{s=0}^{\infty}\left|\frac{a_{\ell-1+s}}{a_{n}}\right| R^{s} \sum_{\substack{i_{1} \ldots i_{\ell} \geq 0, i_{1}+i_{2}+\ldots+i_{\ell}=s}} 1 \\
& =\sum_{s=0}^{\infty}\left|\frac{a_{\ell-1+s}}{a_{n}}\right| R^{s}\left|\binom{-\ell}{s}\right| . \tag{2.6}
\end{align*}
$$

If $k \geq j$ then all indices $\ell-1+s \geq n$, so (2.2) gives

$$
\begin{aligned}
\left|\frac{f_{j, n+k}}{a_{n}}\right| & \leq \sum_{s=0}^{\infty} \rho_{n+1}^{-(\ell-1-n+s)} R^{s}\left|\binom{-\ell}{s}\right| \\
& =\rho_{n+1}^{-(\ell-1-n)}\left(1-R / \rho_{n+1}\right)^{-\ell}
\end{aligned}
$$

Then

$$
\begin{equation*}
\left(\rho_{n} \rho_{n+1}\right)^{\frac{k-j}{2}}\left|\frac{f_{j, n+k}}{a_{n}}\right| \leq\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{\frac{k-j}{2}}\left(1-R / \rho_{n+1}\right)^{-(n+1+k-j)} \tag{2.7}
\end{equation*}
$$

If $k<j$, then we split into those indices $<$ and $\geq n-1$, and use the appropriate inequalities in (2.2):

$$
\begin{aligned}
\left|\frac{f_{j, n+k}}{a_{n}}\right| & \leq \sum_{s=0}^{j-k-1} \rho_{n}^{-(\ell-1-n+s)} R^{s}\left|\binom{-\ell}{s}\right|+\sum_{s=j-k}^{\infty} \rho_{n+1}^{-(\ell-1-n+s)} R^{s}\left|\binom{-\ell}{s}\right| \\
& \leq \sum_{s=0}^{j-k-1} \rho_{n}^{-(k-j+s)} R^{s}\left|\binom{-\ell}{s}\right|+\sum_{s=j-k}^{\infty} \rho_{n}^{-(k-j+s)} R^{s}\left|\binom{-\ell}{s}\right| \\
& =\rho_{n}^{-(k-j)}\left(1-R / \rho_{n}\right)^{-\ell} .
\end{aligned}
$$

Then

$$
\left(\rho_{n} \rho_{n+1}\right)^{\frac{k-j}{2}}\left|\frac{f_{j, n+k}}{a_{n}}\right| \leq\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{\frac{|k-j|}{2}}\left(1-R / \rho_{n}\right)^{-(n+1+k-j)}
$$

Since $\rho_{n} \leq \rho_{n+1}$, this and (2.7) give (2.4).
(b) From (2.6) with $\ell=n+1$,

$$
\begin{aligned}
\left|\frac{f_{j, n+j}}{a_{n}}-1\right| & \leq \sum_{s=1}^{\infty}\left|\frac{a_{n+s}}{a_{n}}\right| R^{s}\left|\binom{-n-1}{s}\right| \\
& \leq \sum_{s=1}^{\infty}\left(R / \rho_{n+1}\right)^{s}\left|\binom{-n-1}{s}\right|=\left(1-R / \rho_{n+1}\right)^{-(n+1)}-1
\end{aligned}
$$

In estimating the denominators, we need the notion of diagonal dominance: a matrix

$$
B=\left[b_{j k}\right]_{1 \leq j, k \leq n}
$$

is called diagonally dominant if for all $1 \leq j \leq n$, we have

$$
\left|b_{j j}\right|>\sum_{k=1, k \neq j}^{n}\left|b_{j k}\right|
$$

We shall use the basic fact that a diagonally dominant matrix has nonzero determinant [17, p. 373].

## Lemma 2.3

Assume that for some $\varepsilon \in\left(0, \frac{1}{2}\right)$, infinite sequence of integers $\mathcal{S}$, and $n=j_{i}, i \in \mathcal{S}$,

$$
\begin{equation*}
\frac{\rho_{n}}{\rho_{n+1}} \leq \frac{1}{9}(1-\varepsilon) \tag{2.8}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{n=j_{i}, i \in \mathcal{S}} \frac{\rho_{n}}{n}=\infty \tag{2.9}
\end{equation*}
$$

Then for any $R>0$, and all $\Lambda_{n} \subset \overline{B_{R}}$, we have for large enough $n=j_{i}, i \in \mathcal{S}$,

$$
\begin{equation*}
\inf _{|z| \leq R}\left|q_{n}\left(\Lambda_{n}, z\right)\right|>0 \tag{2.10}
\end{equation*}
$$

## Proof

Let us assume that the integers $\left\{j_{i}\right\}=\left\{j_{i}(f)\right\}$ and $\left\{\rho_{n}\right\}$ are chosen as above. Assume that $n=j_{i}$ for some $i$. We use (1.9):

$$
q_{n}\left(\Lambda_{n}, z\right)=\operatorname{det}[\mathbf{c} B]
$$

where $\mathbf{c}$ is an $(n+1) \times 1$ column vector, and $B$ is an $(n+1) \times n$ matrix:

$$
\mathbf{c}=\left[\prod_{\ell=1}^{j-1}\left(z-z_{\ell}\right)\right]_{1 \leq j \leq n+1} ; B=\left[f_{j-1, n+k-1}\right]_{\substack{1 \leq j \leq n+1 ; \\ 2 \leq k \leq n+1}}
$$

We divide the 2 nd, 3 rd, $\ldots,(n+1)$ st column in $[\mathbf{c} B]$ by $a_{n}$, and multiply the $j$ th row by $\left(\rho_{n+1} \rho_{n}\right)^{-j / 2}$ and $k$ th column by $\left(\rho_{n+1} \rho_{n}\right)^{k / 2}$ for all $j, k$. Then we obtain

$$
q_{n}\left(\Lambda_{n}, z\right) a_{n}^{-n}=\operatorname{det}[\hat{\mathbf{c}} \hat{B}]
$$

where
$\hat{\mathbf{c}}=\left[\left(\rho_{n+1} \rho_{n}\right)^{(1-j) / 2} \prod_{\ell=1}^{j-1}\left(z-z_{\ell}\right)\right]_{1 \leq j \leq n+1} ; \hat{B}=\left[\left(\rho_{n+1} \rho_{n}\right)^{(k-j) / 2} \frac{f_{j-1, n+k-1}}{a_{n}}\right]_{\substack{1 \leq j \leq n+1 ; \\ 2 \leq k \leq n+1}} ;$

Let $R>0,|z| \leq R$, and all $\left|z_{j}\right| \leq R$. We now show that this last matrix $[\hat{\mathbf{c}} \hat{B}]$ is diagonally dominant for $n=j_{i}$ and $i$ large enough. Consider the $j$ th row. If $j=1$, its diagonal element is 1 . For $j \geq 2$, the diagonal element is

$$
\begin{equation*}
\frac{f_{j-1, n+j-1}}{a_{n}}=1+\varepsilon_{j, n} \tag{2.11}
\end{equation*}
$$

where by the previous lemma, and by (2.9),

$$
\begin{equation*}
\left|\varepsilon_{j, n}\right| \leq\left(1-R / \rho_{n+1}\right)^{-n}-1 \rightarrow 0 \text { as } n \rightarrow \infty \tag{2.12}
\end{equation*}
$$

uniformly in $j$. Now consider the sum of the absolute values of the non-diagonal elements in the $j$ th row of $[\hat{\mathbf{c}} \hat{B}]$, namely

$$
\tau_{j}:=\left(\rho_{n+1} \rho_{n}\right)^{(1-j) / 2}\left|\prod_{\ell=1}^{j-1}\left(z-z_{\ell}\right)\right|+\left(\sum_{k=2}^{j-1}+\sum_{k=j+1}^{n+1}\right)\left(\rho_{n+1} \rho_{n}\right)^{(k-j) / 2}\left|\frac{f_{j-1, n+k-1}}{a_{n}}\right| .
$$

Of course, if $j=1$, the first term and first sum are omitted. Using that $|z| \leq R$, and all $\left|z_{k}\right| \leq R$, and (2.4), we continue this as

$$
\begin{aligned}
\tau_{j} & \leq\left(\frac{2 R}{\left(\rho_{n+1} \rho_{n}\right)^{1 / 2}}\right)^{j-1}+\left(\sum_{k=2}^{j-1}+\sum_{k=j+1}^{n+1}\right)\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{\frac{|k-j|}{2}}\left(1-R / \rho_{n}\right)^{-(n+1+k-j)} \\
& \leq \frac{2 R}{\left(\rho_{n+1} \rho_{n}\right)^{1 / 2}}+\left(1-R / \rho_{n}\right)^{-2 n-2} 2 \sum_{\ell=1}^{\infty}\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{\ell / 2} \\
& =\frac{2 R}{\left(\rho_{n+1} \rho_{n}\right)^{1 / 2}}+\left(1-R / \rho_{n}\right)^{-2 n-2} \frac{2\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{1 / 2}}{1-\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{1 / 2}} \\
& <o(1)+(1+o(1)) \frac{\frac{2}{3}(1-\varepsilon)^{1 / 2}}{1-\frac{1}{3}(1-\varepsilon)^{1 / 2}}<(1+o(1))(1-\varepsilon)^{1 / 2}
\end{aligned}
$$

by (2.8) and (2.9). In view of (2.11), (2.12), we have diagonal dominance of $[\hat{\mathbf{c}} \hat{B}]$, and then (2.10) follows.

## Proof of Theorem 1.4

Now for $n=j_{i}$, for some $i \geq 1$, we have

$$
\begin{gathered}
\left|a_{n}\right|=K / \prod_{\ell=1}^{n} \rho_{\ell} \geq K / \rho_{n}^{n} \\
\Rightarrow \liminf _{n \rightarrow \infty, n=j_{i}} \rho_{n}^{1 / n} \geq \liminf _{n \rightarrow \infty, n=j_{i}} K^{1 / n^{2}} /\left|a_{n}\right|^{1 / n^{2}} \geq 3 /(1-\varepsilon)^{1 / 2},
\end{gathered}
$$

for some $\varepsilon>0$, by (1.7). Thus $\rho_{j_{i}}$ grows roughly at least as fast as $\left(3(1-\varepsilon)^{1 / 2}\right)^{j_{i}}$. Next, for $n=j_{i}$,

$$
\begin{aligned}
\left|a_{n}\right| & =\frac{K}{\rho_{1}^{n}} \prod_{\ell=1}^{n} \frac{\rho_{1}}{\rho_{\ell}}=\frac{K}{\rho_{1}^{n}} \prod_{\ell=2}^{n}\left(\frac{\rho_{1}}{\rho_{2}} \frac{\rho_{2}}{\rho_{3}} \frac{\rho_{3}}{\rho_{4}} \ldots \frac{\rho_{\ell-1}}{\rho_{\ell}}\right) \\
& =\frac{K}{\rho_{1}^{n}}\left(\frac{\rho_{1}}{\rho_{2}}\right)^{n-1}\left(\frac{\rho_{2}}{\rho_{3}}\right)^{n-2}\left(\frac{\rho_{3}}{\rho_{4}}\right)^{n-3} \cdots \frac{\rho_{n-1}}{\rho_{n}} .
\end{aligned}
$$

Then from (1.7), for some $\varepsilon>0$,

$$
\begin{aligned}
\frac{(1-\varepsilon)^{1 / 2}}{3} & \geq \limsup _{n \rightarrow \infty}\left|a_{n}\right|^{1 / n^{2}} \\
& \geq \liminf _{n \rightarrow \infty}\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{[(n-1)+(n-2)+(n-3) \ldots+1] / n^{2}} \\
& =\liminf _{n \rightarrow \infty}\left(\frac{\rho_{n}}{\rho_{n+1}}\right)^{1 / 2} .
\end{aligned}
$$

So for some infinite sequence of integers $\mathcal{S}$,

$$
\frac{\rho_{n}}{\rho_{n+1}} \leq \frac{1-\varepsilon}{9}, n \in \mathcal{S} .
$$

So we have (2.8). But since $\rho_{n+1}=\rho_{n}$ unless $n=j_{i}$ and $n+1=j_{i}+1$ for some $i$, so, as above, $\rho_{n}=\rho_{j_{i}}$ grows at least as fast as $(3(1-\varepsilon))^{j_{i}}$. Then (2.9) also follows.
Now let $S>R>0$. It follows from the previous lemma that for $z \in B_{S}$ and $\Lambda_{n} \subset B_{R}$, we have for large enough $n \in \mathcal{S}$, that $\left|q_{n}\left(\Lambda_{n}, z\right)\right|>0$, so $R_{n}\left(\Lambda_{n}, z\right)$ has no poles in $B_{S}$. Then the uniform convergence in compact subsets of $B_{S}$ follows easily from the contour integral error formula for multipoint Padé approximation [2].

We turn to the proof of Theorem 1.1, and first introduce some notation. Recall that $\mathcal{A}$ denotes the space of entire functions, with metric defined by (1.1). Given $R>0, n \geq 1$, we let
$\mathcal{B}_{n, R}=\left\{f \in \mathcal{A}: q_{n}\left(\Lambda_{n}, z\right)\right.$ has full degree $n$ and no zeros in $\overline{B_{R}}$ whenever $\left.\Lambda_{n} \subset \overline{B_{R}}\right\}$.
Also, let

$$
\mathcal{C}_{n, R}=\bigcup_{j=n}^{\infty} \mathcal{B}_{j, R} .
$$

## Lemma 2.4

For each $n$ and $R>0, \mathcal{C}_{n, R}$ is open and dense in $\mathcal{A}$.

## Proof

We first show that each $\mathcal{B}_{n, R}$ is open, and then the openness of $\mathcal{C}_{n, R}$ follows. Fix an $n$ and $f \in \mathcal{B}_{n, R}$. Since we need to indicate dependence of the multipoint Padé denominators on $f$, we use the notation $q_{n}\left(f, \Lambda_{n}, z\right)$ in this proof only. By compactness, and the continuity of $q_{n}\left(f, \Lambda_{n}, z\right)$ in $\Lambda_{n}$ as long as it has full degree (as follows from (1.8), (1.9)), we see that

$$
\min \left\{\left|q_{n}\left(f, \Lambda_{n}, z\right)\right|: z \in \overline{B_{R}}, \Lambda_{n} \subset \overline{B_{R}}\right\}>0
$$

Moreover, by our hypothesis that the denominators have full degree, all their leading coefficients are non-zero, and then also from (1.9).

$$
\min \left\{\left|\operatorname{det}\left[f_{j-1, n+k}\right]_{1 \leq j, k \leq n}\right|: \Lambda_{n} \subset \overline{B_{R}}\right\}>0
$$

If we consider entire $g$ with $d^{*}(f, g)$ small enough, then the Maclaurin series coefficients of $g$ will be as close to those of $f$ as we please, and consequently all finite differences $g_{j-1, n+k}$ will be close to the corresponding differences for $f$. Then we can ensure that also

$$
\min \left\{\left|\operatorname{det}\left[g_{j-1, n+k}\right]_{1 \leq j, k \leq n}\right|: \Lambda_{n} \subset \overline{B_{R}}\right\}>0 .
$$

By the same token, considering the formula (1.9), we can also ensure that

$$
\min \left\{\left|q_{n}\left(g, \Lambda_{n}, z\right)\right|: z \in \overline{B_{R}}, \Lambda_{n} \subset \overline{B_{R}}\right\}>0
$$

Thus also $g \in \mathcal{B}_{n, R}$. So each $\mathcal{B}_{n, R}$ is open, and hence each $\mathcal{C}_{n, R}$ is open.
The denseness is somewhat more difficult. Fix now some $f \in \mathcal{A}$. We shall construct $g \in \mathcal{C}_{n, R}$ with $d^{*}(f, g)$ as small as we please. Let us assume that the integers $\left\{j_{i}\right\}=\left\{j_{i}(f)\right\}$ and $\left\{\rho_{n}\right\}=\left\{\rho_{n}(f)\right\}$ are chosen as above. Choose now some large positive integer $i_{0}$. Note that by choice of our $\left\{\rho_{j}\right\}$ above,

$$
\left|a_{n}\right| \leq K / \prod_{j=1}^{n} \rho_{j}(f) \text { for } n \leq j_{i_{0}}(f)
$$

and we have equality when $n=j_{k}$, some $1 \leq k \leq i_{0}$. Now define $\hat{\rho}_{j}$ for $j>j_{i_{0}}$ by

$$
\hat{\rho}_{j}=10^{j-j_{i_{0}}} \rho_{j_{i_{0}}} .
$$

Also define for $n>j_{i_{0}}$,

$$
\hat{a}_{n}=a_{j_{i_{0}}} / \prod_{j=j_{i_{0}}+1}^{n} \hat{\rho}_{j}=a_{j_{i_{0}}} \rho_{j_{i_{0}}}^{-\left(n-j_{i_{0}}\right)} 10^{-\left(n-j_{i_{0}}\right)\left(n-j_{i_{0}}+1\right) / 2}
$$

and

$$
g(z)=\sum_{j=0}^{j_{i_{0}}} a_{j} z^{j}+\sum_{j=j_{i_{0}}+1}^{\infty} \hat{a}_{j} z^{j} .
$$

Then $g$ is entire (of order 0 ), and
$d^{*}(f, g) \leq \sup \left\{\left|a_{n}-a_{j_{i_{0}}} \rho_{j_{i_{0}}}^{-\left(n-j_{i_{0}}\right)} 10^{-\left(n-j_{i_{0}}\right)\left(n-j_{i_{0}}+1\right) / 2}\right|^{1 / n}: n>j_{i_{0}}\right\}$.

Straightforward estimation shows that by choosing $i_{0}$ large enough, this can be made as small as we please. Next, as $g$ and $f$ have the same series coefficients up to the coefficient of $z^{j_{i_{0}}}$, we see that

$$
j_{k}(g)=j_{k}(f), k \leq i_{0} \text { and } \rho_{n}(g)=\rho_{n}(f), n \leq j_{i_{0}}
$$

Next, if $n>m \geq j_{i_{0}}$, we see that

$$
\begin{aligned}
\left(\frac{\left|\hat{a}_{n}\right|}{\left|\hat{a}_{m}\right|}\right)^{1 /(n-m)} & =\left(\prod_{j=m+1}^{n}\left(\rho_{j_{i_{0}}}^{-1} 10^{-\left(j-j_{i_{0}}\right)}\right)\right)^{1 /(n-m)} \\
& =\rho_{j_{i_{0}}}^{-1} 10^{j_{i_{0}}}\left(10^{-n(n+1) / 2+m(m+1) / 2}\right)^{1 /(n-m)} \\
& =\rho_{j_{i_{0}}}^{-1} 10^{j_{i_{0}}} 10^{-(n-m)(n+m+1) /(2(n-m))} \\
& =\rho_{j_{i_{0}}}^{-1} 10^{j_{i_{0}}-(n+m+1) / 2}
\end{aligned}
$$

which is maximal for a given $m$ and $n>m$, iff $n=m+1$. It follows easily that

$$
j_{i_{0}+k}(g)=j_{i_{0}}(f)+k, k \geq 1
$$

and for $n>j_{i_{0}}$,

$$
\rho_{n}(g)=\hat{\rho}_{n}=10^{n-j_{i_{0}}} \rho_{j_{i_{0}}} .
$$

Then for $n \geq i_{0}$,

$$
\frac{\rho_{n+1}(g)}{\rho_{n}(g)}=10
$$

and

$$
\lim _{n \rightarrow \infty} \rho_{n}(g)^{1 / n}=10
$$

It then follows from Lemma 2.3, that for large enough $n$ and all $\Lambda_{n} \subset$ $\overline{B_{R}}, q_{n}\left(g, \Lambda_{n}, z\right)$ has no zeros in $\overline{B_{R}}$. Thus $g \in \mathcal{B}_{n, R}$ for all large enough $n$, and in particular, $g \in \mathcal{C}_{n, R}$, while $g$ may be made as close to the given $f$ as we please, by choosing $i_{0}$ large enough. As $f \in \mathcal{A}$ is arbitrary, so $\mathcal{C}_{n, R}$ is dense.

## Proof of Theorem 1.1

Let

$$
\mathcal{C}=\bigcap_{\ell=1}^{\infty} \bigcap_{n=1}^{\infty} \mathcal{C}_{n, \ell}
$$

and

$$
\mathcal{E}=\mathcal{A} \backslash \mathcal{C}=\bigcup_{\ell=1}^{\infty} \bigcup_{n=1}^{\infty} \mathcal{A} \backslash \mathcal{C}_{n, \ell} .
$$

Here since $\mathcal{C}_{n, \ell}$ is open and dense, $\mathcal{E}=\mathcal{A} \backslash \mathcal{C}$ is a countable union of closed nowhere dense sets, and is an $F_{\sigma}$ set. Next if $f \in \mathcal{A} \backslash \mathcal{E}$, then $f \in$ $\mathcal{C}$, so $f \in \mathcal{C}_{n, \ell}$ for all $n, \ell$. Then we can choose an increasing sequence
of integers $\left\{n_{\ell}\right\}_{\ell \geq 1}$ such that $f \in \mathcal{B}_{n_{\ell}, \ell}$ for $\ell \geq 1$. Then $q_{n_{\ell}}\left(\Lambda_{n_{\ell}}, z\right)$ has full degree $n$ and no zeros in $\overline{B_{\ell}}$ whenever $\Lambda_{n_{\ell}} \subset \overline{B_{\ell}}$. This gives the desired uniform convergence of $\left\{R_{n_{\ell}}\left(\Lambda_{n_{\ell}}, \cdot\right)\right\}_{\ell \geq 1}$ whenever $\Lambda_{n_{\ell}} \subset \overline{B_{R}}$, some $R>0$.

## 3. Proof of Theorem 1.2

We proceed partly as in [20]. Let $a_{j} \neq 0, j \geq 1$, and

$$
\begin{equation*}
\sigma_{j}=a_{j-1} a_{j+1} / a_{j}^{2}, j \geq 1 \tag{3.1}
\end{equation*}
$$

For integers $t \geq-n+1$, we let

$$
\begin{equation*}
r_{n, t}=\frac{a_{n+t}}{a_{n}}\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{t} . \tag{3.2}
\end{equation*}
$$

## Lemma 3.1

(a)

$$
\begin{equation*}
r_{n, t}=\sigma_{n}^{|t| / 2} \prod_{\ell=1}^{|t|-1} \sigma_{n+\ell \operatorname{sign}(t)}^{|t|-\ell} \tag{3.3}
\end{equation*}
$$

(b) Assume that for $j \geq J$,

$$
\begin{equation*}
\left|\sigma_{j}\right| \leq \chi<1 \tag{3.4}
\end{equation*}
$$

Then for $n \geq 1$ and $t \geq-n-1$ such that $\min \{n, n+t+1\} \geq J$,

$$
\begin{equation*}
\left|r_{n, t}\right| \leq \chi^{t^{2} / 2} \tag{3.5}
\end{equation*}
$$

(c) If (3.5) holds for $j \geq J$, then for some $C_{0}=C_{0}(J)$, and all $n \geq J$, and $t=0, \pm 1, \pm 2, \ldots$ such that $n+t>0$,

$$
\begin{equation*}
\left|r_{n, t}\right| \leq C_{0} \chi^{t^{2} / 2} \tag{3.6}
\end{equation*}
$$

## Proof

(a) If $t>0$, we use

$$
\frac{a_{j+1}}{a_{j}}=\sigma_{j} \frac{a_{j}}{a_{j-1}}
$$

so

$$
\begin{align*}
\frac{a_{n+t}}{a_{n}} & =\prod_{k=0}^{t-1} \frac{a_{n+k+1}}{a_{n+k}} \\
& =\prod_{k=0}^{t-1}\left(\sigma_{n+k} \sigma_{n+k-1} \ldots \sigma_{n+1} \frac{a_{n+1}}{a_{n}}\right) \\
& =\left(\frac{a_{n+1}}{a_{n}}\right)^{t} \sigma_{n+1}^{t-1} \sigma_{n+2}^{t-2} \ldots \sigma_{n+t-1} \tag{3.7}
\end{align*}
$$

If $t<0$, we use

$$
\frac{a_{j-1}}{a_{j}}=\sigma_{j} \frac{a_{j}}{a_{j+1}},
$$

so

$$
\begin{aligned}
\frac{a_{n+t}}{a_{n}} & =\prod_{k=1}^{|t|} \frac{a_{n-k}}{a_{n-k+1}} \\
& =\prod_{k=1}^{|t|}\left(\sigma_{n-k+1} \sigma_{n-k+2} \ldots \sigma_{n} \frac{a_{n}}{a_{n+1}}\right) \\
& =\left(\frac{a_{n}}{a_{n+1}}\right)^{|t|} \sigma_{n}^{|t|} \sigma_{n-1}^{|t|-1} \ldots \sigma_{n+1-|t|} .
\end{aligned}
$$

This and (3.7) easily give the identity (3.3).
(b) This follows directly from (a), as $n+\ell \operatorname{sign}(t) \geq \min \{n, n+t-1\} \geq$ $J$ in the product, so we can apply the bound (3.4).
(c) Assume

$$
C_{1}=\sup _{j \geq 1}\left|\sigma_{j}\right|
$$

This also follows directly from (a). Indeed, using (3.4),

$$
\left|r_{n, t}\right| \leq \chi^{|t| / 2}\left(\prod_{\substack{1 \leq \ell \leq|t|-1 ; \\ n+\ell \operatorname{sign}(t) \geq J}} \chi^{|t|-\ell}\right) \prod_{\substack{1 \leq \ell \leq|t|-1 ; \\ n+\ell \operatorname{sign}(t)<J}} C_{1}^{|t|-\ell}
$$

which easily gives the result, as there are $O\left(J^{2}\right)$ factors of $C_{1}$ arising from $\ell$ where $n+\ell \operatorname{sign}(t)<J$.

Next for given $n$ and $j \geq 0, k \geq 0$, let

$$
\begin{equation*}
b_{j, k}=\frac{f_{j, n+k}}{a_{n}}\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{k-j} \tag{3.8}
\end{equation*}
$$

where $f_{j, n+k}$ is the divided difference in (1.8).

## Lemma 3.2

Assume all $\left|z_{j}\right| \leq R$. Assume also (3.4) holds for $j \geq J$.
(a) There exists $M$ depending only on $R, \chi, J$, such that for $0 \leq j, k \leq$ n, satisfying

$$
\begin{equation*}
n+k-j \geq M \tag{3.9}
\end{equation*}
$$

we have for some constant $C_{2}$ depending only on $R, \chi, J$,

$$
\begin{equation*}
\left|b_{j, k}\right| \leq \chi^{(k-j)^{2} / 2}\left\{1+C_{2}(n+1+k-j) \chi^{n+1+k-j}\right\} . \tag{3.10}
\end{equation*}
$$

(b) For $n \geq M$ and $0 \leq j \leq n$,

$$
\begin{equation*}
\left|b_{j, j}-1\right| \leq C_{2} n \chi^{n} \tag{3.11}
\end{equation*}
$$

(c) We have for some constant $C_{4}$ depending only on $R, \chi, J$, and all $0 \leq j, k \leq n$,

$$
\begin{equation*}
\left|b_{j, k}\right| \leq C_{4} \chi^{(k-j)^{2} / 2} \tag{3.12}
\end{equation*}
$$

## Proof

(a) We may assume that $M>J$. Let $\ell=n+1+k-j$. Using (2.6),

$$
\left|\frac{f_{j, n+k}}{a_{n}}\right| \leq \sum_{s=0}^{\infty}\left|\frac{a_{\ell-1+s}}{a_{n}}\right| R^{s}\left|\binom{-\ell}{s}\right| .
$$

Then as all $\ell-1+s \geq J$, we can apply our definitions (3.2), (3.8), and the bound (3.5) and deduce

$$
\begin{aligned}
\left|b_{j, k}\right| & \leq \sum_{s=0}^{\infty}\left(\left|\frac{a_{n}}{a_{n+1}}\right| \sigma_{n}^{1 / 2}\right)^{-s}\left|r_{n, k-j+s}\right| R^{s}\left|\binom{-\ell}{s}\right| \\
& \leq \sum_{s=0}^{\infty}\left(\left|\frac{a_{n}}{a_{n+1}}\right| \sigma_{n}^{1 / 2}\right)^{-s} \chi^{(k-j+s)^{2} / 2} R^{s}\left|\binom{-\ell}{s}\right| \\
& =\chi^{(k-j)^{2} / 2} \sum_{s=0}^{\infty}\left(\left|\frac{a_{n+1}}{a_{n}}\right| \sigma_{n}^{-1 / 2} \chi^{k-j} R\right)^{s} \chi^{s^{2} / 2}\left|\binom{-\ell}{s}\right| \\
& \leq \chi^{(k-j)^{2} / 2} \sum_{s=0}^{\infty}\left(\left|\frac{a_{n+1}}{a_{n}}\right| \sigma_{n}^{-1 / 2} \chi^{k-j+1 / 2} R\right)^{s}\left|\binom{-\ell}{s}\right| .
\end{aligned}
$$

Here

$$
\begin{align*}
& \left|\frac{a_{n+1}}{a_{n}}\right| \sigma_{n}^{-1 / 2} \chi^{k-j+1 / 2} R \\
= & \sigma_{n} \sigma_{n-1} \sigma_{n-2} \ldots \sigma_{J}\left|\frac{a_{J}}{a_{J-1}}\right| \sigma_{n}^{-1 / 2} \chi^{k-j+1 / 2} R \\
\leq & \chi^{n+1+k-j-J}\left|\frac{a_{J}}{a_{J-1}}\right| R \\
= & C_{3} \chi^{\ell} \tag{3.13}
\end{align*}
$$

where $C_{3}=\chi^{-J}\left|\frac{a_{J}}{a_{J+1}}\right| R$. So

$$
\begin{aligned}
\left|b_{j, k}\right| & \leq \chi^{(k-j)^{2} / 2} \sum_{s=0}^{\infty}\left(C_{3} \chi^{\ell}\right)^{s}\left|\binom{-\ell}{s}\right| \\
& \leq \chi^{(k-j)^{2} / 2}\left(1-C_{3} \chi^{\ell}\right)^{-\ell}
\end{aligned}
$$

provided $C_{3} \chi^{\ell}<1$. We now use the inequality

$$
\begin{equation*}
(1-x)^{-\ell}-1 \leq 2 \ell x \text { for } x \in\left[0, \frac{1}{2 \ell}\right], \ell \geq 2 \tag{3.14}
\end{equation*}
$$

This gives

$$
\left|b_{j, k}\right| \leq \chi^{(k-j)^{2} / 2}\left\{1+2 C_{3} \ell \chi^{\ell}\right\}
$$

provided

$$
\begin{equation*}
C_{3} \chi^{\ell} \leq \frac{1}{2 \ell} \tag{3.15}
\end{equation*}
$$

As $\chi<1$, this last inequality holds for $\ell=n+1+k-j \geq M$ and some threshhold $M$.
(b) Here, proceeding as in (a), we see that for $n \geq J$, with $\ell=n+1$,

$$
\begin{aligned}
\left|\frac{f_{j, n+j}}{a_{n}}-1\right| & \leq \sum_{s=1}^{\infty}\left|\frac{a_{\ell-1+s}}{a_{n}}\right| R^{s}\left|\binom{-\ell}{s}\right| \\
& \leq \sum_{s=1}^{\infty}\left(\left|\frac{a_{n}}{a_{n+1}}\right| \sigma_{n}^{1 / 2}\right)^{-s}\left|r_{n, s}\right| R^{s}\left|\binom{-\ell}{s}\right| \\
& \leq \sum_{s=1}^{\infty}\left(\left|\frac{a_{n}}{a_{n+1}}\right| \sigma_{n}^{1 / 2}\right)^{-s} \chi^{s^{2} / 2} R^{s}\left|\binom{-\ell}{s}\right| \\
& \leq \sum_{s=1}^{\infty}\left(\left|\frac{a_{n+1}}{a_{n}}\right| \sigma_{n}^{-1 / 2} R \chi^{1 / 2}\right)^{s}\left|\binom{-\ell}{s}\right| \\
& \leq\left(1-C_{3} \chi^{n} R\right)^{-n-1}-1,
\end{aligned}
$$

as above. Using (3.14), we continue this for $n \geq M$, and uniformly in $j$, as

$$
\left|b_{j, j}-1\right| \leq C_{2} n \chi^{n}
$$

(c) As above, we let $\ell=n+1+k-j$. If $n+1+k-j \geq M$, we can apply (a). So assume $\ell=n+1+k-j<M$. Now

$$
\left|\binom{-\ell}{s}\right|=\binom{\ell+s-1}{s} \leq 2^{\max \{\ell+s-1,0\}} \leq 2^{\ell+s}
$$

Proceeding as in (a), but using Lemma 3.1(c),

$$
\begin{aligned}
\left|b_{j, k}\right| & \leq \sum_{s=0}^{\infty}\left(\left|\frac{a_{n}}{a_{n+1}}\right| \sigma_{n}^{1 / 2}\right)^{-s}\left|r_{n, k-j+s}\right| R^{s}\left|\binom{-\ell}{s}\right| \\
& \leq C_{0} \sum_{s=0}^{\infty}\left(\left|\frac{a_{n}}{a_{n+1}}\right| \sigma_{n}^{1 / 2}\right)^{-s} \chi^{(k-j+s)^{2} / 2} R^{s} 2^{\ell+s} \\
& \leq C_{0} 2^{\ell} \chi^{(k-j)^{2} / 2} \sum_{s=0}^{\infty}\left(2\left|\frac{a_{n+1}}{a_{n}}\right| \sigma_{n}^{-1 / 2} \chi^{k-j+1 / 2} R\right)^{s} \chi^{\left(s^{2}-s\right) / 2}
\end{aligned}
$$

As at (3.13), and since $0 \leq \ell=n+1+k-j<M$,
$2\left|\frac{a_{n+1}}{a_{n}}\right| \sigma_{n}^{-1 / 2} \chi^{k-j+1 / 2} R \leq 2 R \chi^{n+k-j-J+1}\left|\frac{a_{J}}{a_{J-1}}\right| \leq 2 R \chi^{-J}\left|\frac{a_{J}}{a_{J-1}}\right|=2 C_{3}$,
so

$$
\left|b_{j, k}\right| \leq C_{0} 2^{M} \chi^{(k-j)^{2} / 2} \sum_{s=0}^{\infty}\left(2 C_{3}\right)^{s} \chi^{\left(s^{2}-s\right) / 2}
$$

Then (3.12) follows.

## Lemma 3.3

Assume that (1.4) holds with $\chi<\rho_{0}$, where $\rho_{0}=0.4559 \ldots$ is the root of (1.5). For any $R>0$, and $\Lambda_{n} \subset \overline{B_{R}}$, we have for large enough $n$,

$$
\begin{equation*}
\inf _{|z| \leq R}\left|q_{n}\left(\Lambda_{n}, z\right)\right|>0 \tag{3.16}
\end{equation*}
$$

## Proof

We use (1.9):

$$
q_{n}\left(\Lambda_{n}, z\right)=\operatorname{det}[\mathbf{c} B]
$$

where $\mathbf{c}$ is a column vector, and $B$ is an $(n+1) \times n$ matrix:

$$
\mathbf{c}=\left[\prod_{\ell=1}^{j-1}\left(z-z_{\ell}\right)\right]_{1 \leq \ell \leq n+1} ; B=\left[f_{j-1, n+k-1}\right]_{\substack{1 \leq j \leq n+1 ; \\ 2 \leq k \leq n+1}}
$$

We divide the 2 nd, 3 rd, $\ldots,(n+1)$ st column by $a_{n}$, and multiply the $j$ th row by $\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{-j}$ and $k$ th column by $\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{k}$, for all $j, k$. Then we obtain

$$
\begin{equation*}
q_{n}\left(\Lambda_{n}, z\right) a_{n}^{-n}=\operatorname{det}[\hat{\mathbf{c}} \hat{B}], \tag{3.17}
\end{equation*}
$$

where

$$
\hat{\mathbf{c}}=\left[\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{1-j} \prod_{\ell=1}^{j-1}\left(z-z_{\ell}\right)\right]_{1 \leq j \leq n+1}
$$

and after an index change,

$$
\begin{equation*}
\hat{B}=\left[\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{k-j} \frac{f_{j, n+k}}{a_{n}}\right]_{\substack{0 \leq j \leq n ; \\ 1 \leq k \leq n}}=\left[b_{j, k}\right]_{\substack{0 \leq j \leq n ; \\ 1 \leq k \leq n}} \tag{3.18}
\end{equation*}
$$

Here we are using the notation (3.8). Let $R>0,|z| \leq R$, and all $\left|z_{j}\right| \leq R$. We now show that $[\hat{\mathbf{c}} \hat{B}]$ is diagonally dominant. Consider the $(j+1)$ st row, where $0 \leq j \leq n$. If $j=0$, its diagonal element is 1 . For $j \geq 1$, the diagonal element is

$$
\begin{equation*}
b_{j, j}=1+\varepsilon_{j, n} \tag{3.19}
\end{equation*}
$$

where by Lemma 3.2(b),

$$
\begin{equation*}
\left|\varepsilon_{j, n}\right| \leq C_{2} n \chi^{n} \rightarrow 0 \text { as } n \rightarrow \infty, \tag{3.20}
\end{equation*}
$$

uniformly in $j$. Now consider the sum of the absolute values of the non-diagonal elements in the $(j+1)$ st row, namely

$$
\tau_{j}=\left(\left|\frac{a_{n+1}}{a_{n}} \sigma_{n}^{-1 / 2}\right|\right)^{j}\left|\prod_{\ell=1}^{j}\left(z-z_{\ell}\right)\right|+\left(\sum_{k=1}^{j-1}+\sum_{k=j+1}^{n}\right)\left|b_{j, k}\right| .
$$

Of course, if $j=1$, the first term and first sum are omitted. First let us assume that

$$
n-j \geq\left[\frac{2 \log n}{|\log \chi|}\right]=\Delta_{n}
$$

say. Then for large enough $n$, we have (3.9) for all terms in the sum, so can then estimate

$$
\begin{aligned}
\tau_{j} & \leq\left(\left|\frac{a_{n+1}}{a_{n}} \sigma_{n}^{-1 / 2}\right| 2 R\right)^{j}+\left(\sum_{k=1}^{j-1}+\sum_{k=j+1}^{n+1}\right) \chi^{(k-j)^{2} / 2}\left\{1+C_{2}(n+1+k-j) \chi^{n+1+k-j}\right\} \\
& \leq o(1)+(1+o(1)) 2 \sum_{\ell=1}^{\infty} \chi^{\ell^{2} / 2} \leq 1-\varepsilon
\end{aligned}
$$

for some small enough $\varepsilon$. Recall that $\chi<\rho_{0}$, where $\rho_{0}$ is the root of (1.5). Using (3.19), (3.20), we see then that the $(j+1, j+1)$ element in the $(j+1)$ st row has absolute value larger than $\tau_{j}$, as required for diagonal dominance. We still have to handle those terms for which $n-j \leq \Delta_{n}$. Here most of $\tau_{j}$ can be estimated as above:

$$
\left(\left|\frac{a_{n+1}}{a_{n}} \sigma_{n}^{-1 / 2}\right| 2 R\right)^{j}+\sum_{k=\Delta_{n}+1}^{n+1} \chi^{(k-j)^{2} / 2}\left\{1+C_{2}(n+1+k-j) \chi^{n+1+k-j}\right\} \leq 1-\varepsilon
$$

Next, for $2 \leq k \leq \Delta_{n}$, and $n-j \leq \Delta_{n}$, we have $j-k \geq n-2 \Delta_{n}$, so

$$
\begin{aligned}
& \sum_{k=2}^{\Delta_{n}}\left|b_{j, k}\right| \\
\leq & C_{3} \sum_{k=2}^{\Delta_{n}} \chi^{(k-j)^{2} / 2} \\
\leq & C_{3} \Delta_{n} \chi^{\left(n-2 \Delta_{n}\right)^{2} / 2} \rightarrow 0,
\end{aligned}
$$

as $n \rightarrow \infty$, by Lemma 3.2(c). Again we obtain diagonal dominance.

## Proof of Theorem 1.2

Given any $r>0$, the interpolants $R_{n}\left(\Lambda_{n}, z\right)$ have no poles in $B_{r}$ for large enough $n$. Then as above, the locally uniform convergence follows.

## 4. Proof of Theorem 1.3

This case is more delicate than the proof of Theorem 1.2. We have to multiply by a suitable matrix before proving diagonal dominance. Accordingly for $q \in \mathbb{C}$, and $n \geq 1$, let

$$
A_{n}(q)=\left[q^{(k-j)^{2} / 2}\right]_{1 \leq j, k \leq n}
$$

The determinant of this matrix can be reduced to that of a Vandermonde matrix by multiplying rows and columns by suitable factors. It is known that (see e.g. [21, p. 326])

$$
\operatorname{det}\left(A_{n}(q)\right)=\prod_{j=1}^{n-1}\left(1-q^{j}\right)^{n-j}
$$

When this matrix is non-singular, its inverse admits uniform bounds on its entries. More precisely, the $(k, \ell)$ entry in $A_{n}(q)^{-1}$ admits the bound

$$
\begin{equation*}
\left|\left(A_{n}(q)^{-1}\right)_{k \ell}\right| \leq S|q|^{|\ell-k| / 2} \tag{4.1}
\end{equation*}
$$

where

$$
S=2 \prod_{j=1}^{\infty}\left(\frac{1+|q|^{j}}{1-|q|^{j}}\right)^{2}
$$

See [21, Lemma 2.1, pp. 326-327]. For integers $t \geq-n+1$, we define $r_{n, t}$ by (3.2). We begin with bounds and asymptotics for $r_{n, t}$ :

## Lemma 4.1

Let $L \geq 1$. We have for $|t| \leq L$,

$$
r_{n, t}=q^{t^{2} / 2}\left(1+\varepsilon_{n, t}\right)
$$

where

$$
\begin{equation*}
\max _{|t| \leq L}\left|\varepsilon_{n, t}\right| \rightarrow 0 \text { as } n \rightarrow \infty . \tag{4.2}
\end{equation*}
$$

## Proof

Since the total number of $\sigma$ factors in the right-hand side of (3.3) is $|t| / 2+(|t|-1)+(|t|-2)+\ldots+1=|t|^{2} / 2$, the assertion follows from our hypothesis that $\sigma_{m} \rightarrow q$ as $m \rightarrow \infty$.

Next for given $n$ and $j \geq 0, n+k \geq 0$, define $b_{j, k}$ by (3.8).

## Lemma 4.2

Let $L \geq 1$ and $\chi \in(|q|, 1)$. For $1 \leq j, k \leq n$, we can write

$$
\begin{equation*}
b_{j, k}=q^{(k-j)^{2} / 2}+\delta_{j, k}, \tag{4.3}
\end{equation*}
$$

where
(a) if $|j-k| \leq L$,

$$
\begin{equation*}
\eta_{L}^{*}=\max _{|j-k| \leq L}\left|\delta_{j, k} / q^{(k-j)^{2} / 2}\right| \rightarrow 0 \text { as } n \rightarrow \infty \tag{4.4}
\end{equation*}
$$

(b) for all $0 \leq j, k \leq n$,

$$
\begin{equation*}
\left|\delta_{j, k}\right| \leq C_{4} \chi^{(k-j)^{2} / 2} \tag{4.5}
\end{equation*}
$$

where $C_{4}$ is independent of $n, j, k$ and of $L$ above.
Proof
(a) Let $\ell=n+1+k-j$, where $|j-k| \leq L$. As at (2.6),

$$
\begin{aligned}
\left|\frac{f_{j, n+k}}{a_{n}}-\frac{a_{\ell-1}}{a_{n}}\right| & =\left|\frac{a_{\ell-1}}{a_{n}} \sum_{i_{1} \ldots i_{\ell} \geq 0 \text { with at least one } i_{j} \geq 1} z_{j+1}^{i_{1}} z_{j+2}^{i_{2}} \ldots z_{j+\ell+1}^{i_{\ell}} \frac{a_{\ell-1+i_{1}+i_{2}+\ldots+i_{\ell}}}{a_{\ell-1}}\right| \\
& \leq\left|\frac{a_{n+k-j}}{a_{n}}\right| \sum_{s=1}^{\infty} R^{s}\left|\frac{a_{\ell-1+s}}{a_{\ell-1}}\right|\left|\binom{-\ell}{s}\right| .
\end{aligned}
$$

Proceeding as in Lemma 3.2, and using Lemma 3.1(c),

$$
\begin{aligned}
\left|b_{j, k}-r_{n, k-j}\right| & \leq\left|r_{n, k-j}\right| \sum_{s=1}^{\infty} R^{s}\left|\frac{a_{\ell}}{a_{\ell-1}} \sigma_{\ell-1}^{-1 / 2}\right|^{s}\left|r_{\ell-1, s}\right|\left|\binom{-\ell}{s}\right| \\
& \leq\left|r_{n, k-j}\right| \sum_{s=1}^{\infty} R^{s}\left|\frac{a_{\ell}}{a_{\ell-1}} \sigma_{\ell-1}^{-1 / 2}\right|^{s} C_{4} \chi^{s^{2} / 2}\left|\binom{-\ell}{s}\right| \\
& \leq\left|r_{n, k-j}\right| C_{4}\left\{\left(1-R\left|\frac{a_{\ell}}{a_{\ell-1}} \sigma_{\ell-1}^{-1 / 2}\right| \chi^{1 / 2}\right)^{-\ell}-1\right\} \\
& \leq\left|r_{n, k-j}\right| C_{5}(n+k-j) \chi^{n+k-j} \\
& \leq C_{6}\left|r_{n, k-j}\right| n \chi^{n},
\end{aligned}
$$

by (3.14). Then Lemma 4.1 gives

$$
\begin{aligned}
\left|\delta_{j, k}\right| & =\left|b_{j, k}-q^{(k-j)^{2} / 2}\right| \\
& \leq\left|b_{j, k}-r_{n, k-j}\right|+\left|r_{n, k-j}-q^{(k-j)^{2} / 2}\right| \\
& \leq\left|r_{n, k-j}\right|\left\{C_{6} n \chi^{n}+C_{7} \max _{|t| \leq L}\left|\varepsilon_{n, t}\right|\right\} \\
& \leq \eta_{L}^{*}|q|^{(k-j)^{2} / 2}
\end{aligned}
$$

where $\eta_{L}^{*} \rightarrow 0$ as $L \rightarrow \infty$.
(b) Choose $J$ such that $\left|\sigma_{j}\right| \leq \chi$ for $j \geq J$. Note that $J$ is independent of $L$ in (a). Using Lemma 3.2(c), for all $0 \leq j, k \leq n$,

$$
\left|b_{j, k}\right| \leq C_{4} \chi^{(k-j)^{2} / 2}
$$

so

$$
\left|\delta_{j, k}\right| \leq\left|b_{j, k}\right|+|q|^{(k-j)^{2} / 2} \leq\left(C_{4}+1\right) \chi^{(k-j)^{2} / 2}
$$

## Proof of Theorem 1.3

It suffices to show that given $R>0$ and $\Lambda_{n} \subset B_{R}, n \geq 1$, then for large enough $n$,

$$
\inf _{z \in B_{R}}\left|q_{n}\left(\Lambda_{n}, z\right)\right|>0
$$

We use (3.17), namely

$$
\begin{equation*}
q_{n}\left(\Lambda_{n}, z\right) a_{n}^{-n}=\operatorname{det}[\hat{\mathbf{c}} \hat{B}] \tag{4.6}
\end{equation*}
$$

where $[\hat{\mathbf{c}} \hat{B}]$ is given by (3.18). We partition the column $\hat{\mathbf{c}}$ and matrix $\hat{B}$ as follows:

$$
q_{n}\left(\Lambda_{n}, z\right) a_{n}^{-n}=\operatorname{det}\left[\begin{array}{cc}
1 & \mathbf{f} \\
\mathbf{d} & A_{n}(q)+\Delta
\end{array}\right]
$$

where $\mathbf{d}$ is an $n$ by 1 column vector; $\mathbf{f}$ is an $n$ by 1 row vector; and $\Delta$ is an $n$ by $n$ matrix with "small" entries. Thus

$$
\begin{align*}
\mathbf{d} & =\left[\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{-j} \prod_{\ell=1}^{j}\left(z-z_{\ell}\right)\right]_{1 \leq j \leq n} ; \\
\mathbf{f} & =\left[\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{k} \frac{f_{0, n+k}}{a_{n}}\right]_{1 \leq k \leq n}^{T}=\left[b_{0, k}\right]_{1 \leq k \leq n} ; \\
\Delta & =\left[\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{k-j} \frac{f_{j, n+k}}{a_{n}}\right]_{1 \leq j, k \leq n}-A_{n}(q) \\
& =\left[b_{j, k}\right]_{1 \leq j, k \leq n}-A_{n}(q)=\left[\delta_{j, k}\right]_{1 \leq j, k \leq n} . \tag{4.7}
\end{align*}
$$

We multiply the determinant above by

$$
\operatorname{det}\left[\begin{array}{cc}
1 & -\mathbf{f} A_{n}(q)^{-1} \\
\mathbf{0} & A_{n}(q)^{-1}
\end{array}\right]=\operatorname{det} A_{n}(q)^{-1}
$$

We then see that

$$
\begin{align*}
& q_{n}\left(\Lambda_{n}, z\right) a_{n}^{-n}\left(\operatorname{det} A_{n}(q)\right)^{-1} \\
= & \operatorname{det}\left[\begin{array}{cc}
1 & \mathbf{f} \\
\mathbf{d} & A_{n}(q)+\Delta
\end{array}\right]\left[\begin{array}{cc}
1 & -\mathbf{f} A_{n}(q)^{-1} \\
\mathbf{0} & A_{n}(q)^{-1}
\end{array}\right] \\
= & \operatorname{det}\left[\begin{array}{cc}
1 & \mathbf{0}^{T} \\
\mathbf{d} & -\mathbf{d f} A_{n}(q)^{-1}+I+\Delta A_{n}(q)^{-1}
\end{array}\right] \\
= & \operatorname{det}\left[I-\operatorname{df} A_{n}(q)^{-1}+\Delta A_{n}(q)^{-1}\right] . \tag{4.8}
\end{align*}
$$

We shall show the matrix in this last determinant is diagonally dominant. First,

$$
\begin{aligned}
& \mathbf{d f} A_{n}(q)^{-1} \\
= & {\left[\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{-j}\left(\prod_{\ell=1}^{j}\left(z-z_{\ell}\right)\right) b_{0, k}\right]_{1 \leq j, k \leq n} A_{n}(q)^{-1} }
\end{aligned}
$$

so the sum of the absolute values of elements in the $j$ th row of the matrix $\mathbf{d f} A_{n}(q)^{-1}$ is, using (4.5) and (4.1),

$$
\begin{align*}
& \left|\left(\frac{a_{n}}{a_{n+1}} \sigma_{n}^{1 / 2}\right)^{-j} \prod_{\ell=1}^{j}\left(z-z_{\ell}\right)\right|\left|\sum_{\ell=1}^{n} \sum_{k=1}^{n} b_{0, k}\left(A_{n}(q)^{-1}\right)_{k \ell}\right| \\
\leq & S C_{3}\left(2 R\left|\frac{a_{n+1}}{a_{n}}\right|\right)^{j} \sum_{\ell=1}^{n} \sum_{k=1}^{n} \chi^{k^{2} / 2}|q|^{|k-\ell| / 2} \\
\leq & 2 S C_{3}\left(1-|q|^{1 / 2}\right)^{-1}\left(\sum_{k=1}^{\infty} \chi^{k^{2} / 2}\right)\left(2 R\left|\frac{a_{n+1}}{a_{n}}\right|\right)^{j} \\
\leq & C_{4}\left(2 R\left|\frac{a_{n+1}}{a_{n}}\right|\right)^{j} \tag{4.9}
\end{align*}
$$

Next, the sum of absolute values of elements in the $j$ th row of the matrix $\Delta A_{n}(q)^{-1}$ is bounded above by

$$
\begin{aligned}
& \sum_{k=1}^{n} \sum_{\ell=1}^{n}\left|\delta_{j, \ell} A_{n}(q)_{\ell, k}^{-1}\right| \\
\leq & S \sum_{k=1}^{n} \sum_{\ell=1}^{n}\left|\delta_{j, \ell}\right||q|^{|k-\ell| / 2} \\
\leq & 2 S\left(1-|q|^{1 / 2}\right)^{-1} \sum_{\ell=1}^{n}\left|\delta_{j, \ell}\right| \\
\leq & 2 S\left(1-|q|^{1 / 2}\right)^{-1}\left\{\eta_{L}^{*} \sum_{\ell:|j-\ell| \leq L}|q|^{(j-\ell)^{2} / 2}+C_{3} \sum_{\ell:|j-\ell|>L} \chi^{(j-\ell)^{2} / 2}\right\} \\
\leq & 2 S\left(1-|q|^{1 / 2}\right)^{-1}\left\{2 \eta_{L}^{*}\left(1-|q|^{1 / 2}\right)^{-1}+C_{3} \chi^{L^{2} / 2}\right\}
\end{aligned}
$$

by (4.2) and (4.5). It is crucial here that $C_{3}$ is independent of $L$. Choosing $L$ large enough, and then using that $\eta_{L}^{*} \rightarrow 0$ as $n \rightarrow \infty$, we see that this row sum may be made $<\frac{1}{4}$ for large enough $n$. Together with (4.9), this shows that the matrix in the determinant in (4.8) is diagonally dominant, and we are done.
