## 1.1 Introduction

The proof of Kuratowski's theorem provides us with a template for an algorithm that tests whether a graph is planar. There is an algorithm of Hopcroft and Tarjan that checks 3-connectivity in linear time. Note that a quadratic algorithm is easy because it is possible to check 2-connectivity in linear time. In this lecture we will describe a quadratic-time algorithm (with respect to the number of vertices in the graph) that tests whether a graph has a planar drawing. We note that there exist linear-time planarity algorithms, but they are much more complicated than the quadratic one described here.

### 1.1.1 Background Definitions

**Definition 1.1** Let  $H \subseteq G$ . An  $H$ -bridge of  $G$  is a subgraph  $B$  of  $G$  such that either:

- (i)  $B \cong K_2$  with both vertices but not its edge in  $H$ , or
- (ii)  $B$  consists of a component of  $G \setminus V(H)$ , all edges from that component to  $H$  and all ends of those edges. The vertices of  $V(B) \cap V(H)$  are called vertices of attachment or simply attachments of  $B$ . (Figure 1)

Notice that bridges can only share vertices of attachment with other bridges, and furthermore, bridges are edge-disjoint from  $H$ . In addition, bridges play an important role in growing planar subgraphs. One characteristic used to describe the process of adding bridges to a graph is that of  $f$ -admissibility.

**Definition 1.2** Let  $H$  be a plane graph and let  $H \subseteq G$ . For  $f \in F(H)$ , we say that an  $H$ -bridge  $B$  is  $f$ -admissible if all the attachments of  $B$  belong to the boundary of  $f$ .

## 1.2 The Algorithm

To test planarity, it suffices to test each block separately, and it suffices to restrict ourself to 2-connected graphs. Consider the following algorithm, which given a 2-connected graph, returns either a planar drawing of  $G$  or a statement that no such drawing exists:

PLANAR( $G$ )

1. Let  $H$  be a cycle in  $G$  (this exists since  $G$  is a 2-connected graph). Pick a planar drawing of  $H$ .
2. If there is no  $H$ -bridge, i.e.  $H = G$ , then  $H$  is a planar drawing of  $G$ .

3. If some  $H$ -bridge is  $f$ -admissible for no face  $f$ , then output NO and stop.
4. If some  $H$ -bridge is  $f$ -admissible for a unique face  $f \in F(H)$ , then let  $B$  be one such bridge. Otherwise let  $B$  be any  $H$ -bridge.

---

5. Pick a nontrivial sub-path  $P$  of  $B$  with ends in  $H$  and otherwise disjoint from  $H$ .
6. Let  $H := H \cup P$ . The sub-path  $P$  may not be unique and we make an arbitrary choice if there is one. Draw  $P$  in any face  $f$  so that  $B$  is  $f$ -admissible.
7. Return to step 2.

### 1.3 Proof of Correctness

We will show that if  $G$  is planar, then for every  $H$  in the algorithm, the planar drawing of  $H$  can be extended to some planar drawing of  $G$ . (Recall that the same graph can have different drawings.)

To begin the proof, suppose that the planar drawing of  $H$  can be extended to some planar drawing of  $G$ . We must show that this property holds for  $H \cup P$ , where  $B, f$  and  $P$  are given in the description of the algorithm. Let  $\Gamma$  be a drawing of  $G$  that extends  $H$ . In  $\Gamma$ , the bridge  $B$  lies in a face  $f'$  of  $H$ . If  $f = f'$ , then  $\Gamma$  gives a planar drawing that extends  $H \cup P$ .

Therefore, we may assume that  $f \neq f'$ . Also note that the bridge  $B$  is both  $f$  and  $f'$ -admissible. The algorithm drew the path  $P$  in the face  $f$ , so  $B$  is  $f$ -admissible, and in the drawing,  $\Gamma$ , the bridge  $B$  is drawn in the face  $f'$ , so  $B$  is  $f'$ -admissible. This implies that for every bridge  $B'$ , there exist at least two faces,  $g$ , such that  $B'$  is  $g$ -admissible. Otherwise, we would have been forced by the algorithm to select the bridge that was admissible in only one face and  $f = f'$ .

Let  $\Gamma'$  be obtained from  $\Gamma$  by swapping all  $H$ -bridges that are both  $f$  and  $f'$  admissible. Specifically, if an  $H$ -bridge that is both  $f$  and  $f'$ -admissible is originally drawn in  $f$ , it is now drawn in  $f'$  and vice versa. There are two situations that could cause a problem. The first problem arises when the swapped bridge could not attach the same way in  $f$  and  $f'$ . However, this problem can not occur because the attachments of a bridge always come in the same cyclic order in  $f$  and  $f'$ . This consistent ordering can be seen when the bridge is "flipped" from face  $f$  to  $f'$ . (Figure 2)

The second problem occurs when we could produce an obstruction. Specifically, the bridge that is swapped from  $f$  to  $f'$  (or  $f'$  to  $f$ ) may be forced to have edges cross with a bridge only admissible in exactly one of  $f, f'$ . To rectify this problem, consider the following two mutually exclusive definitions that describe how two bridges can produce a crossing.

**Definition 1.3** *Two bridges  $B$  and  $B'$  are skew if they have the same set of attachments and each has exactly three attachments. (Figure 3)*

**Definition 1.4** *Two bridges  $B$  and  $B'$  overlap on a face  $f$  if there exist distinct vertices  $a, b, c, d$  on the boundary of  $f$  in order, such that  $a$  and  $c$  are attachments of  $B$  and  $b$  and  $d$  are attachments to  $B'$ . (Figure 4)*

If we have an obstruction in the drawing  $\Gamma'$ , then there are two bridges  $D_1$  and  $D_2$  that are skew or overlap. Without loss of generality, suppose that  $D_1$  is the bridge that did not swap faces and let  $D_2$  be the newly inserted bridge. Also, without loss of generality suppose that in  $\Gamma'$ ,  $D_1$  and  $D_2$  are drawn in  $f$ . So  $D_2$  is  $f$  and  $f'$ -admissible, but  $D_1$  is only  $f$ -admissible. By the construction of the algorithm, we know that besides  $f$ ,  $D_1$  is admissible in another face, call it  $f'' \neq f$ . Note that  $f'' \neq f'$  as  $D_1$  is not  $f'$  admissible.

The bridges  $D_1$  and  $D_2$  cannot be skew because one is  $f'$  admissible and the other is not. As a result,  $D_1$  and  $D_2$  can not share the same attachment set. Thus, they overlap on the face  $f$ . In addition, define  $a$  and  $c$  to be vertices of attachment of  $D_1$  to face  $f$  and define  $b$  and  $d$  to be vertices of attachment of  $D_2$  to face  $f$ . Furthermore, we name these vertices so that their order around face  $f$  is  $a, b, c, d$ . Notice that vertices  $a$  and  $c$  are also contained in  $f''$  and vertices  $b$  and  $d$  are contained in  $f'$ . Let  $v$  be a vertex in  $f$  and draw edges from  $v$  to  $a, b, c$  and  $d$ . Then add an edge drawn inside  $f'$  between vertices  $b$  and  $d$  and an edge drawn inside  $f''$  between vertices  $a$  and  $c$ . (These edges are drawn as dashed lines in Figure 5.) This produces a subdivision of  $K_5$  in the plane.

As a result, we have shown that  $\Gamma'$  is a planar drawing and it extends  $H \cup P$ , completing the proof.
