

Homogeneous linear systems with constant coefficients and eigenvectors

We consider the first order homogeneous linear system with constant coefficients:

$$\frac{d\vec{x}}{dt} = A\vec{x}, \quad \text{where } \vec{x} \in \mathbb{R}^n, A \in \mathbb{R}^{n \times n}.$$

* if $n=1$

We have just one equation of the form $y' = qy$. Using that this equation is separable or using an integrating factor, we prove that the solution is:

$$y(t) = y(0) e^{\int q(t) dt}.$$

* if $n \geq 2$

If we want to apply the same method, we need to compute e^{tA} , but tA is a matrix!

We define the exponential of a matrix by:

$$e^{tA} = \sum_{k \geq 0} \frac{(tA)^k}{k!}$$

$$(e^B = \sum_{k \geq 0} \frac{B^k}{k!}, \text{ with } B = tA)$$

This term is 0 if $k=0$

With this definition, we can check

$$(e^{tA})' = \frac{d}{dt} \left(\sum_{k \geq 0} \frac{t^k A^k}{k!} \right) = \sum_{k \geq 0} \frac{k t^{k-1} A^k}{k!} = \left(\sum_{k \geq 1} \frac{t^{k-1}}{(k-1)!} A^{k-1} \right) A$$

$$\text{by the change of variable } j=k-1: \quad (e^{tA})' = \left(\sum_{j \geq 0} \frac{t^j}{j!} A^j \right) A = e^{tA} \cdot A$$

Therefore: The solution of this equation $\frac{d\vec{x}}{dt} = A\vec{x}$

is $\vec{x}(t) = e^{tA} \vec{x}(0)$

Problem: How do we compute e^{tA} ?

(we the formula, we need to compute $A^k, \forall k \geq 0$)

(:() too hard for our matrix except if ...)

Solution: it's easier to compute A^t if A is diagonal

\Rightarrow

DIAGONALIZATION

$A \in \mathbb{R}^{n \times n}$, if we have n independent eigenvectors $\vec{v}_1, \dots, \vec{v}_n$ associated to the eigenvalues $\lambda_1, \dots, \lambda_n$, then for $P = (\vec{v}_1, \dots, \vec{v}_n)$ and the diagonal matrix $D = \begin{pmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_n \end{pmatrix}$, we have:

$$A = P D P^{-1}$$

Let us prove then that the solution is thus:

$$\vec{x}(t) = e^{tA} \vec{x}(0) = P e^{tD} P^{-1} \vec{x}(0) \quad (1)$$

To prove this, we have two methods:

* Method 1

We introduce the change of variables $\vec{q} = P^{-1} \vec{x}$
(fun fact: we don't have to compute P^{-1})

Then:

$$\begin{aligned} \frac{d\vec{q}}{dt} &= \frac{d}{dt} (P^{-1} \vec{x}) \quad \rightarrow P^{-1} \text{ is a } \underline{\text{constant}} \text{ matrix} \\ &= P^{-1} \frac{d}{dt} \vec{x} \quad \rightarrow \frac{d}{dt} \vec{x} = A \vec{x} \\ &= P^{-1} A \vec{x} \quad \rightarrow A = P D P^{-1} \\ &= \underbrace{P^{-1} P}_{=I_n} \underbrace{D P^{-1}}_{=\vec{q}} \quad \rightarrow \\ &= D \vec{q} \end{aligned}$$

Therefore the solution is given by $\vec{q}(t) = e^{tD} \vec{q}(0)$

and using that $\vec{x}(t) = P \vec{q}(t)$ (and $\vec{q}(0) = P^{-1} \vec{x}(0)$)

we obtain $\vec{x}(t) = P \vec{q}(t) = P e^{tD} P^{-1} \vec{x}(0)$

* Method 2

By definition and using the diagonalization:

$$e^{tA} = e^{tPD P^{-1}} = e^{t(P(D)P^{-1})} = \sum_{k \geq 0} \frac{(P(D)P^{-1})^k}{k!}$$

$$\text{But } (P(D)P^{-1})^k = (P \underbrace{D}_{\text{In}} \underbrace{P^{-1}}_{\text{In}})(P \underbrace{D}_{\text{In}} \underbrace{P^{-1}}_{\text{In}}) \dots P \underbrace{D}_{\text{In}} \underbrace{P^{-1}}_{\text{In}} \quad (\text{k times}) \\ = P(D)^k P^{-1}$$

$$\text{Therefore: } e^{tA} = \sum_{k \geq 0} P \left(\frac{(tD)^k}{k!} \right) P^{-1}$$

$$= P \left(\sum_{k \geq 0} \frac{(tD)^k}{k!} \right) P^{-1} = Pe^{tD} P^{-1}$$

$$\text{and } \vec{x}(t) = e^{tA} \vec{x}(0) = Pe^{tD} P^{-1} \vec{x}(0)$$

Now we have to compute e^{tD}

$$D = \begin{pmatrix} d_1 & & \\ & \ddots & \\ & & d_n \end{pmatrix} \text{ is diagonal, thus } D^k = \begin{pmatrix} d_1^k & & \\ & \ddots & \\ & & d_n^k \end{pmatrix}.$$

$$\text{Therefore: } e^{tD} = \sum_{k \geq 0} \frac{(tD)^k}{k!} = \sum_{k \geq 0} \frac{t^k}{k!} \begin{pmatrix} d_1^k & & \\ & \ddots & \\ & & d_n^k \end{pmatrix}$$

$$\text{(by linearity)} \quad = \begin{pmatrix} \sum_{k \geq 0} \frac{t^k d_1^k}{k!} & & \\ & \ddots & \\ & & \sum_{k \geq 0} \frac{t^k d_n^k}{k!} \end{pmatrix}$$

$$\boxed{e^{tD} = \begin{pmatrix} e^{td_1} & & \\ & \ddots & \\ & & e^{td_n} \end{pmatrix}}$$

We computed the exponential of a matrix, yeah! ☺

$$\text{And now: } \vec{x}(t) = Pe^{tD} P^{-1} \vec{x}(0) \quad \text{and } P = (\vec{v}_1 \dots \vec{v}_n)$$

$$= (\vec{v}_1 \dots \vec{v}_n) \begin{pmatrix} e^{td_1} & & \\ & \ddots & \\ & & e^{td_n} \end{pmatrix} P^{-1} \vec{x}(0)$$

(it is almost over!)

Now we can remark that:

$$P e^{tD} = (\vec{v}_1 \dots \vec{v}_n) \begin{pmatrix} e^{dt} & & 0 \\ & \ddots & \\ 0 & & e^{dt} \end{pmatrix} = (e^{dt} \vec{v}_1 \dots e^{dt} \vec{v}_n).$$

* $P^{-1} \vec{x}(0) = \begin{pmatrix} c_1 \\ \vdots \\ c_n \end{pmatrix}$ is a constant vector.

Therefore, finally:

$$\boxed{\vec{x} = c_1 e^{dt} \vec{v}_1 + c_2 e^{dt} \vec{v}_2 + \dots + c_n e^{dt} \vec{v}_n}$$

the general solution of $\frac{d}{dt} \vec{x} = A \vec{x}$ when A

is diagonalizable, where:

- $\vec{v}_1 \dots \vec{v}_n$ are n independent eigenvectors of A

- $d_1 \dots d_n$ are the n corresponding eigenvalues

- c_1, \dots, c_n are constant.
