Clustering

**FIGURE 14.4.** Simulated data in the plane, clustered into three classes (represented by orange, blue and green) by the K-means clustering algorithm.
Outline

1. Similarity

2. Clustering algorithms
14.1 – Proximity matrices

Data: \( \{x_i\}_{i=1}^N \)

Proximity matrix: \( D \in \mathbb{R}^{N \times N}, \ d_{ii} = 0 \)

Symmetrization: If \( D \) is not symmetric, we can take \( (D + D^T)/2 \)

Dissimilarities based on attributes:

\[
D(x_i, x_{i'}) = \sum_{j=1}^p d_j(x_{ij}, x'_{ij})
\]

where \( x_{ij} \) is the \( j \)th attribute of the \( i \)th data.
Dissimilarities

- Euclidean distance

\[ d_j(x_{ij}, x'_{ij}) = (x_{ij} - x'_{ij})^2 \]

- More general

\[ d(x_i, x'_i) = l(|x_i - x'_i|) \]

where \( l(\cdot) \) is a monotone-increasing function.

- Based on correlation

\[ \rho(x_i, x'_i) = \frac{\sum_j (x_{ij} - \bar{x}_i)(x'_{ij} - \bar{x}'_i)}{\sqrt{\sum_j (x_{ij} - \bar{x}_i)^2} \sqrt{\sum_j (x'_{ij} - \bar{x}'_i)^2}} \]

where \( \bar{x}_i = \sum_j x_{ij} / p \)
Weighted average

\[ D(x_i, x_{i'}) = \sum_{j=1}^{p} w_j \cdot d_j(x_{ij}, x_{i'j}); \quad \sum_{j=1}^{p} w_j = 1. \]

**FIGURE 14.5.** Simulated data: on the left, K-means clustering (with \( K=2 \)) has been applied to the raw data. The two colors indicate the cluster memberships. On the right, the features were first standardized before clustering. This is equivalent to using feature weights \( 1/[2 \cdot \text{var}(X_j)] \). The standardization has obscured the two well-separated groups. Note that each plot uses the same units in the horizontal and vertical axes.
Outline

1 Similarity

2 Clustering algorithms
Clustering algorithms

- $N$ points: $x_i, i \in \{1, \ldots, N\}$
- $K$ clusters $k \in \{1, \ldots, K\}$
- Encoder $k = C(i)$, that assigns the $i$th point to the $k$th cluster

**Energy functions:**

$$W(C') = \frac{1}{2} \sum_{k=1}^{K} \sum_{C(i) = k} \sum_{C(i') = k} d(x_i, x_{i'}).$$

$$B(C') = \frac{1}{2} \sum_{k=1}^{K} \sum_{C(i) = k} \sum_{C(i') \neq k} d_{ii'}.$$

$$T = \frac{1}{2} \sum_{i=1}^{N} \sum_{i'=1}^{N} d_{ii'} = \frac{1}{2} \sum_{k=1}^{K} \sum_{C(i) = k} \left( \sum_{C(i') = k} d_{ii'} + \sum_{C(i') \neq k} d_{ii'} \right)$$

$$T = W(C) + B(C),$$

$W$ is the in-cluster point scatters, and $W$ is the between-cluster point scatters. $T$ is the total point scatters, which is a constant given the data, independent of cluster assignment.
Clustering algorithms

**Clustering:** maximize $W(C)$ or minimize $B(C)$

**Problem:** solving this optimization problem directly is combinatorial. The number of distinct assignments is

$$S(N, K) = \frac{1}{K!} \sum_{k=1}^{K} (-1)^{K-k} \binom{K}{k} k^N.$$  

$S(10, 4) = 34,105$ and $S(19, 4) \approx 10^{10}$
K-means

Euclidean distance:

\[ d(x_i, x_{i'}) = \sum_{j=1}^{p} (x_{ij} - x_{i'j})^2 = \|x_i - x_{i'}\|^2 \]

Within-point scatter:

\[ W(C') = \frac{1}{2} \sum_{k=1}^{K} \sum_{C(i)=k} \sum_{C(i')=k} \|x_i - x_{i'}\|^2 = \sum_{k=1}^{K} N_k \sum_{C(i)=k} \|x_i - \bar{x}_k\|^2, \]

where \( \bar{x}_k = (\bar{x}_{1k}, \ldots, \bar{x}_{pk}) \) is the mean vector associated with the \( k \)th cluster and \( N_k = \sum_{i=1}^{N} I(C(i) = k) \).
Iterative descent algorithm

Minimization:

\[ C^* = \min_C \sum_{k=1}^{K} N_k \sum_{C(i)=k} \|x_i - \bar{x}_k\|^2 \]

where for any subset \( S \)

\[ \bar{x}_S = \arg\min_m \sum_{i \in S} \|x_i - m\|^2. \]

Enlarged minimization:

\[ \min_{C,\{m_k\}} \sum_{k=1}^{K} N_k \sum_{C(i)=k} \|x_i - m_k\|^2. \]
Algorithm 14.1 K-means Clustering.

1. For a given cluster assignment $C$, the total cluster variance (14.33) is minimized with respect to $\{m_1, \ldots, m_K\}$ yielding the means of the currently assigned clusters (14.32).

2. Given a current set of means $\{m_1, \ldots, m_K\}$, (14.33) is minimized by assigning each observation to the closest (current) cluster mean. That is,

$$C(i) = \arg\min_{1 \leq k \leq K} ||x_i - m_k||^2.$$  \hspace{1cm} (14.34)

3. Steps 1 and 2 are iterated until the assignments do not change.
Algorithm iteration

K-medoids

About K-means

- The squared Euclidean distance is used: \( d(x_i, x_{i'}) = \|x_i - x_{i'}\|^2 \), which places the highest influence on the largest distances.
- Not robust against outliers with large distances.

K-medoids: an alternating algorithm that tries to solve

\[
\min_{C, \{i_k\}_1^K} \sum_{k=1}^K \sum_{C(i)=k} d_{ii_k}.
\]
K-medoids

**Algorithm 14.2 K-medoids Clustering.**

1. For a given cluster assignment $C$ find the observation in the cluster minimizing total distance to other points in that cluster:

   $i_k^* = \arg\min_{\{i:C(i)=k\}} \sum_{C(i')=k} D(x_i, x_{i'}).$  \hfill (14.35)

   Then $m_k = x_{i_k^*}, \ k = 1, 2, \ldots, K$ are the current estimates of the cluster centers.

2. Given a current set of cluster centers $\{m_1, \ldots, m_K\}$, minimize the total error by assigning each observation to the closest (current) cluster center:

   $C'(i) = \arg\min_{1 \leq k \leq K} D(x_i, m_k).$  \hfill (14.36)

3. Iterate steps 1 and 2 until the assignments do not change.
Example: country dissimilarities

**TABLE 14.3.** Data from a political science survey: values are average pairwise dissimilarities of countries from a questionnaire given to political science students.
